Abstract: The key transform of the REESSE1+ cryptosystem is \( C_i = (A, W(i))^{x} \mod M \) with \( i \) being only some fixed integer and the sufficiency that a simplified private key is secure at present if \( i \) is a one-to-one function. The sufficiency is expounded from four aspects: indeterminacy of the new \( i \), every necessary with even \( \Omega_i \), or \( \text{gcd}(\Omega_i, \delta) = 1 \), or \( \text{gcd}(\Omega_i, \delta) \equiv 1 \mod a \), and \( \text{gcd}(\Omega_i, \delta) \equiv 0 \mod a \). Last, elaborate a relation between a lever function and a random oracle.

Keywords: Public key cryptosystem; Coprime sequence; Lever function; Continued fraction attack; Random oracle

1 Introduction

Theories of computational complexity such as the class P, the class NP, one-way functions, and trapdoor functions provide public key cryptosystems with foundation stones [1][2][3]. For instance, the RSA cryptosystem is founded on the integer factorization problem (IFP) [4], and the ElGamal cryptosystem is founded on the discrete logarithm problem (DLP) [5]. It appeals to people whether trapdoor functions provide public key cryptosystems with foundation stones [1][2][3]. For instance, the random oracle provides a simplified transform \( C_i = A, W(i) \mod M \) and a new lever function \( \ell(i) \) from \{1, ..., \( n \}\) to \( \Omega_i = \{+/-5, ..., +/-n + 4\} \), where \( +/-n \) means the selection of the “+” or “−” sign, and discuss the necessity of the new \( \ell(i) \) that a simplified private key is secure at present if \( \ell(i) \) is a one-to-one function. The sufficiency is expounded from four aspects: indeterminacy of the new \( \ell(i) \), every necessary with even \( \Omega_i \), or \( \text{gcd}(\Omega_i, \delta) = 1 \), or \( \text{gcd}(\Omega_i, \delta) \equiv 1 \mod a \), and \( \text{gcd}(\Omega_i, \delta) \equiv 0 \mod a \). Last, elaborate a relation between a lever function and a random oracle.

2 Simplified REESSE1+ Encryption Scheme

To probe the indeterminacy of the lever function \( \ell(.) \) from \{1, ..., \( n \}\) to \{+/-5, ..., +/-n + 4\}, let \( \delta = 1 \) in the key transform of the REESSE1+ cryptosystem, and thus we acquire the simplified REESSE1+ encryption scheme.

2.1 Two Definitions

Definition 1: If \( A_1, A_2, ..., A_n \) are \( n \) pairwise distinct positive integers such that \( \forall A, A_i \neq j \), either \( \text{gcd}(A_i, A_j) = 1 \), or \( \text{gcd}(A_i, A_j) = F \neq 1 \) with \( (A_i / F) \mod A_i \) and \( (A_j / F) \mod A_j \), \( \forall k \neq i, j \in \{1, n\} \), these

integers are called a coprime sequence, denoted by \( \{A_1, \ldots, A_n\} \), and shorty \( \{A_i\} \).

Notice that the elements of a coprime sequence are not necessarily pairwise coprime, but a sequence whose elements are pairwise coprime must be a coprime sequence.

**Property 1:** Let \( \{A_1, \ldots, A_n\} \) be a coprime sequence. If randomly select \( m \in [1, n] \) elements \( A_{s_1}, \ldots, A_{s_m} \) from the sequence, then the mapping from a subset \( \{A_{s_1}, \ldots, A_{s_m}\} \) to a subset product \( G = \prod_{i=1}^n A_i \) is one-to-one, namely the mapping from \( b_1 \ldots b_n \) to \( G = \prod_{i=1}^n A_i b_i \) is one-to-one, where \( b_1 \ldots b_n \) is a bit string.

Refer to [6] for its proof.

**Definition 2.** The secret parameter \( \ell(i) \) in the key transform of a public key cryptosystem is called a lever function, if it has the following features:

- \( \ell(.) \) is an injection from the domain \( \{1, \ldots, n\} \) to the codomain \( \Omega \subset \{5, \ldots, M\} \), where \( M \) is large;
- the mapping between \( i \) and \( \ell(i) \) is established randomly without an analytical expression;
- an attacker has to be faced with all the arrangements of \( n \) elements in \( \Omega \) when extracting a related private key from a public key;
- the owner of a related private key only needs to consider the accumulative sum of \( n \) elements in \( \Omega \) when recovering a related plaintext from a ciphertext.

The latter two points manifest that if \( n \) is large enough, it is infeasible for the attacker to search all the permutations of elements in \( \Omega \) exhaustively while the decryption of a normal ciphertext is feasible in some time polynomial in \( n \). Thus, there are the large amount of calculation on \( \ell(i) \) at “a public terminal”, and the small amount of calculation on \( \ell(.) \) at “a private terminal”.

Notice that \( \Phi \) the number of elements of \( \Omega \) is not less than \( n \); \( \Phi \) considering the speed of decryption, the absolute values of all the elements should be comparatively small; \( \Phi \) the lower limit 5 will make seeking the root \( W \) from \( W^{\ell(i)} = A_i^{-1} C_i (\% M) \) face an unsolvable Galois group when the value of \( A_i \leq 1201 \) is easily guessed [7].

### 2.2 Key Generation Algorithm

In the simplified REESSE1+ encryption scheme, we substitute \( \Omega = \{5, 7, \ldots, 2n + 3\} \) with \( \Omega_2 = \{\ldots, n \} \).

Let \( \Omega_2 \) be the set of absolute values of all the elements in \( \Omega_2 \).

Let \( A = \{2, \ldots, P\} \), where \( P = 863, 937, 991, \) or 1201 when \( n = 80, 96, 112, \) or 128.

This algorithm is employed by a certificate authority or the owner of a key pair.

**INPUT:** the integer \( n \); the set \( A \).

S1: Randomly produce \( \Omega_2 \leftarrow \{+/5, \ldots, -(n + 4)\} \).

S2: Randomly produce odd and coprime \( A_1, \ldots, A_n \in A \).

S3: Find a prime \( M > \prod_{i=1}^n A_i \) making \( q^2 \mid M \forall \text{ prime } q \in \Omega_2 \).

S4: Stochastically pick the integer \( W \in (1, \mathcal{M}) \).

S5: Stochastically yield pairwise distinct \( \ell(1), \ldots, \ell(n) \in \Omega_2 \).

S6: Compute \( C_i \leftarrow A_i W^{\ell(i)} \% M \) for \( i = 1, \ldots, n \).

**OUTPUT:** a public key \( (\{C_1, \ldots, C_n\}, M) \); a private key \( (\{A_1, \ldots, A_n\}, W, M) \).

The secret parameter \( \ell(1), \ldots, \ell(n) \) may be discarded.

Notice that at S1, \( \Omega_2 = \{+/5, \ldots, -(n + 4)\} \) indicates that \( \Omega_2 \) is one of 2\(^n\) potential sets, where “+/−” means the selection of the “+” or “−” sign, and in modular \( M \) arithmetic, −\( x \) represents \( M − x \).

### 2.3 Encryption Algorithm

This algorithm is employed by a person who wants to encrypt plaintexts.

**INPUT:** a public key \( (\{C_1, \ldots, C_n\}, M) \); an \( n \)-bit plaintext block \( b_1 \ldots b_n \).

S1: Set \( G \leftarrow 1, i \leftarrow 1 \).

S2: If \( b_i = 1 \) then let \( G \leftarrow GC_i \% M \).

S3: Let \( i \leftarrow i + 1 \).

S4: If \( i \leq n \) then goto S2 else end.

**OUTPUT:** the ciphertext \( G = \prod_{i=1}^n C_i^{b_i} (\% M) \).

**Definition 3:** Given \( G \) and \( (\{C_1, \ldots, C_n\}, M) \), seeking \( b_1 \ldots b_n \) from \( G = \prod_{i=1}^n C_i^{b_i} (\% M) \) is called a subset product problem, shortly SPP [6][8].

Notice that when \( \log M \) $\ll 10^24$, a discrete logarithm can be found in tolerable subexponential time. Let \( g \) be a generator of \( \mathbb{Z}_M^* \), \( G = g^x (\% M) \), \( C_1 = g^a (\% M) \), \( \ldots, C_n = g^a (\% M) \), and then a SPP \( G \)
\[ \prod_{i=1}^{\ell} C^h \pmod{M} \] is degenerated to a subset sum problem
\[ u = b_1 v_1 + \ldots + b_n v_n \pmod{M}. \]

Because the density of the knapsack from the above subset sum problem is less than 1, a simplified REESSE1+ ciphertext \( \mathcal{C} \) is not robust [9], which indicates that only if \( \lceil \log M \rceil \geq 1024 \), can the simplified REESSE1+ cryptoscheme have practical sense.

2.4 Decryption Algorithm

This algorithm is employed by a person who wants to decrypt ciphertexts.

INPUT: a private key \((\{A_1, \ldots, A_n\}, W, M)\); a ciphertext \( \mathcal{C} \).

S1: Set \( X_0 \leftarrow \mathcal{C}, X_1 \leftarrow \mathcal{C}, h \leftarrow 0. \)

S2: If \( 2 \mid X_0 \) then \( X_n \leftarrow X_nW^{-3p} \pmod{M} \), goto S2 else next.

S3: Set \( b_1 \ldots b_n \leftarrow 0, G \leftarrow X_n, i \leftarrow 1. \)

S4: If \( A_i \mid G \) then let \( b_i \leftarrow 1, G \leftarrow G / A_i. \)

S5: Let \( i \leftarrow i + 1. \)
   
   If \( i \leq n \) and \( G \neq 1 \) then goto S4.

S6: If \( G \neq 1 \) then do \( h \leftarrow -b_i, X_0 \leftarrow X_0W^{-1p} \pmod{M}, \) goto S2
   
   else end.

OUTPUT: a plaintext block \( b_1 \ldots b_n. \)

Notice that only if \( \mathcal{C} \) is a true ciphertext, can this algorithm always terminates normally.

3 Necessity of the Lever Function \( \ell(.) \)

We will discuss the necessity of the new lever function \( \ell(.) \) from \( \{1, \ldots, n\} \) to \( \Omega_\ell = \{+/−5, \ldots, +/−(n + 4)\} \) for resisting continued fraction attack and parameter intersection attack.

The necessity of the lever function \( \ell(.) \) means that if a simplified REESSE1+ private key is secure, \( \ell(.) \) as a one-to-one function must exist in the key transform. The equivalent contrapositive assertion is that if \( \ell(.) \) as a one-to-one function does not exist (namely all \( \ell(i) \) is only some integer \( \varrho \)), a simplified REESSE1+ private key will be insecure.

3.1 Continued Fraction Attack on a Simplified Private Key

**Theorem 1:** If \( \alpha \) is an irrational number, \( r, s > 0 \) are two integers, and \( r / s \) is a rational in the lowest terms such that \( |\alpha - r / s| < 1 / (2^s) \), then \( r / s \) is a convergent of the simple continued fraction expansion of \( \alpha \).

Refer to [10] for the proof.

Notice that theorem 1 also holds when \( \alpha \) is a rational number [10].

For a public key cryptosystem, if a private key is insecure, a plaintext must be insecure. Hence, the security of a private key is most foundational [11].

**Definition 4:** Attack on \( C_i = A_iW^{\ell(i)} \pmod{M} \) with \( \ell(i) \in \Omega_\ell = \{+/−5, \ldots, +/−(n + 4)\} \) for \( i = 1, \ldots, n \) by a convergent of the continued fraction of \( G_i / M \), where \( G_i = (C_{1,i} \cdots C_{n,i})(C_{1,j} \cdots C_{n,j})^{-1} \) with \( m \in [1, n − 1] \), \( h \in [1, n − m] \), and \( x_j = y_j \forall j \in [1, m] \) and \( k \in [1, h] \), is called continued fraction attack.

**Property 2:** Let \( \varrho \in [1, M] \) be any integer. If the key transform of the simplified REESSE1+ cryptosystem is \( C_i = A_iW^{\varrho} \pmod{M} \), namely \( \ell(i) = \varrho \) for \( i = 1, \ldots, n \), a simplified REESSE1+ private key \((\{A_1, \ldots, A_n\}, W^{\varrho}) \) is insecure.

**Proof:**

Assume that \( \ell(1) = \ell(2) = \ldots = \ell(n) = \varrho, \) where \( \varrho \) is a fixed integer.

Then, the key transform becomes as
\[ C_i = A_iW^{\varrho} \pmod{M}, \]
and especially when \( \varrho = 1 \), \( C_i = A_iW \pmod{M} \) for \( i = 1, 2, \ldots, n. \)

Since \((\cdot, \cdot)\) is an Abelian group [7], of course, there is
\[ C_i^{-1} = (A_iW^{\varrho})^{-1} \pmod{M}. \]

\[ \forall x \in [1, n − 1], \]

let
\[ G_z = C_iC_z^{-1} \pmod{M}. \]

Substituting \( A_iW^{\varrho} \) and \( A_iW^{\varrho} \) respectively for \( C_i \) and \( C_z \) in the above congruence yields
\[ G_z = A_iW^{\varrho}(A_iW^{\varrho})^{-1} \pmod{M} \]
\[ A_z = A_i \pmod{M} \]
\[ A_n G_z - LM = A_s, \]

where \( L \) is a positive integer.

The either side of the equation is divided by \( A_n M \) gives
\[ \frac{G_z}{M} - \frac{L}{A_n} = A_s / (A_n M). \]  

Due to \( M > \prod_{i=1}^{n} A_i \) and \( A_i \geq 2 \), there is
\[ \frac{G_z}{M} - \frac{L}{A_n} < \frac{1}{A_s (A_n \prod_{i=1}^{n-1} A_i)} = \frac{1}{(2^{n-2} A_s^2)}, \]

that is,
\[ \frac{G_z}{M} - \frac{L}{A_n} < 1 / (2^{n-2} A_s^2). \]  

Evidently, as \( n > 2 \), there is
\[ \frac{G_z}{M} - \frac{L}{A_n} < 1 / (2 A_s^2). \]  

In terms of theorem 1, \( L / A_n \) is a convergent of the continued fraction of \( \frac{G_z}{M} \).

Thus, \( L / A_n \), namely \( A_n \), may be determined by \( (2') \) in polynomial time since the length of the continued fraction will not exceed \( \lceil \lg M \rceil \), and further \( W^\uparrow = C_n A_s^{-1} \) \( (\% M) \) may be computed, which indicates the original coprime sequence \( \{A_1, ..., A_n\} \) with \( A_i \leq P \) can almost be recovered. \( \square \)

Because \( W \) in every \( C_i \) has the same exponent, and the powers of \( W \) and \( W^{-1} \) in any \( C_i C_n^{-1} \% M \) always counteract each other, when \( \ell(i) \) is a fixed integer \( \bar{e} \), there does not exist the indeterministic reasoning problem.

It should be noted that when a convergent of the continued fraction of \( \frac{G_z}{M} \) satisfies \( (2') \), the same \( \ell(i) \) convergents also possibly satisfies \( (2') \), and if so, it will bring about the nonuniqueness of value of \( A_n \). Therefore, we say that \( \{A_1, ..., A_n\} \) with \( A_i \leq P \) can almost be recovered.

### 3.2 Parameter Intersection Attack on a Simplified Private Key

Assume that \( \ell(1) = ... = \ell(n) = \bar{e} \), where \( \bar{e} \) is a fixed integer. Then the key transform turns to \( C_i = A_i W^\bar{e} \) \( (\% M) \) for \( i = 1, ..., n \). Hence, there exists the following attack.

**Algorithm 3.2:**

**INPUT:** a public key \( \{C_1, ..., C_n\} \), \( M \)
**S1:** For \( i = 1, ..., n \) do
  while \( A_i \) traverses \( A \) do
    **S1.1:** compute \( W^\bar{e} \) such that \( W^\bar{e} = C_i A_i^{-1} \) \( (\% M) \);
    **S1.2:** Place the pair \( (W^\bar{e}, A_i) \) into the set \( P_i \).
**S2:** Seek the intersection \( V = V_1 \cap ... \cap V_n \) on \( W^\bar{e} \).
(Not that there \( 1 \leq |V| < |A| \))
**S3:** Extract \( W^\bar{e} \) from \( V \) and corresponding \( A_i \) from \( P_i \).
**S4:** If \( A_1, ..., A_n \) are pairwise coprime then \( W^\bar{e} \) and \( \{A_i\} \) valid.
**OUTPUT:** a private key \( \{A_1, ..., A_n\}, W^\bar{e} \).

It is not difficult to understand that the time complexity of the above attack is dominantly involved in \( S1 \) and \( S2 \). Concretely speaking, the time complexity is \( O(2^n / |P|) \), and polynomial in \( n \).

Section 3.1 and 3.2 manifest that when \( \ell(i) \) is a fixed integer \( \bar{e} \), a related private key can be deduced from a public key, and further a related plaintext can be inferred from a ciphertext. Thus, the one-to-one lever function \( \ell(.) \) is necessary to the security of a simplified REESSE1+ private key.

### 4 Sufficiency of the Lever Function \( \ell(.) \)

The sufficiency of the new lever function \( \ell(.) \) from \( \{1, ..., n\} \) to \( \Omega_n = \{\pm/5, ..., \pm/(n + 4)\} \) for resisting continued fraction attack and parameter intersection attack which are the two most efficient algorithms so far means that if \( \ell(1), ..., \ell(n) \in \Omega_n \) are pairwise distinct, a simplified REESSE1+ private key will be secure.

We will see that continued fraction attack and parameter intersection attack are ineffectual on the security of a private key when \( \Omega_n \) is indeterminate, and even if \( \Omega_n = \{5, ..., n + 4\} \) happens and is known to adversaries, continued fraction attack does not always threaten \( C_i = A_i W^\ell(i) \) \( (\% M) \).

#### 4.1 Indeterminacy of the Lever Function \( \ell(.) \)

According to Section 2.2, if the lever function \( \ell(.) \) exists, we have
\[ C_i = A_i W^\ell(i) \]  

\( (\% M) \), where \( A_i \in A = \{2, ..., P_i\} \), and \( \ell(i) \in \Omega_n = \{\pm/5, ..., \pm/(n + 4)\} \) for \( i = 1, ..., n \).
The lever function $f$ brings adversaries at least two difficulties:

- No method in terms of which one can directly judge whether the power of $W$ in $C_1 \ldots C_n$ is counteracted by the power of $W^{-1}$ in $(C_1 \ldots C_n)^{-1}$ or not;
- No criterion in terms of which one can verify the presupposition of an indeterministic reasoning in polynomial time.

The indeterministic reasoning based on continued fractions means that ones first presuppose that the powers of the parameter $W$ and the inverse $W^{-1}$ counteract each other in a product, and then judge whether the presupposition holds or not by the consequence.

According to Section 3, first select $m \in [1, n-1]$ elements and $h \in [1, n-m]$ other elements from $\{C_1, \ldots, C_n\}$. Let

\[
G_x = C_1 \ldots C_n \ % \ M,
G_y = C_1 \ldots C_n \ % \ M,
\]

where $x_j \neq y_k \ \forall \ j \in [1, m]$ and $k \in [1, h]$.

Let

\[
G_z = G_x G^{-1}_y \ % \ M.
\]

Since $\{f(1), \ldots, f(n)\}$ is any arrangement of $n$ elements in $\Omega_x$, it is impossible to predicate that $G_z$ does not contain the factor $W$ or $W^{-1}$. For a further deduction, we have to presuppose that the power of $W$ in $G_z$ is exactly counteracted by the power of $W^{-1}$ in $G^{-1}_y$, and then,

\[
G_z = (A_1, \ldots, A_n)(A_1', \ldots, A_n')^{-1} \ % \ M
\]

\[
G_x (A_1', \ldots, A_n') = A_1, \ldots, A_n \ % \ M
\]

\[
G_x (A_1', \ldots, A_n') - LM = A_1, \ldots, A_n
\]

\[
G_z / M - L / (A_1, \ldots, A_n) = (A_1, \ldots, A_n) / (M A_1', \ldots, A_n),
\]

where $L$ is a positive integer.

Denoting the product $A_1', \ldots, A_n'$ by $\tilde{A}$, yields

\[
G_z / M - L / \tilde{A} = (A_1, \ldots, A_n) / (M \tilde{A}).
\]

Due to $M > \prod_{i=1}^n A_i$ and $A_i \geq 2$, we have

\[
G_z / M - L / \tilde{A} < 1 / (2^{m-n-h} \tilde{A}^2).
\]

Obviously, when $n > m + h$, (4) may have a variant, namely

\[
G_z / M - L / \tilde{A} < 1 / (2^{m-h} \tilde{A}^2).
\]

Notice that when $n = m + h$, if $M > 2(\prod_{i=1}^n A_i)$, (4) still holds.

Especially, when $n > 3$, $h = 1$, and $m = 2$, there exists

\[
G_z / M - L / A_1 < 1 / (2^{m-3} A_1^2) < 1 / (2 A_1^2).
\]

Obviously, as a discriminant, (4) is stricter than (4') and (4''). (4'') is consistent with theorem 1.

**Property 3:** Let $h + m \leq n$. If $f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h)$, the subset product $\tilde{A} = A_1', \ldots, A_n'$ in (4') will be found in polynomial time.

**Proof:**
\[
f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h)
\]
means that the exponent on $W$ in $C_1 \ldots C_n$ is counteracted by the exponent on $W^{-1}$ in $(C_1 \ldots C_n)^{-1}$, and thus (4') holds.

In terms of theorem 1, $L / \tilde{A}$ is inevitably a convergent of the continued fraction of $G_z / M$, and thus $\tilde{A} = A_1', \ldots, A_n'$ can be found in polynomial time.

Notice that (4'') is insufficient for $f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h)$ (see Property 7), and $\tilde{A}$ is faced with nonuniqueness because there may possibly exist several convergents of the continued fraction of $G_z / M$ which all satisfy (4').

**Property 4 (Indeterminacy of $f$):** Let $h + m \leq n$. $\forall x_1, \ldots, x_m, y_1, \ldots, y_h \in [1, n]$, and $[|W|] \neq \mathcal{M}$.

1. When $f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h)$, and $m \neq h$, there is
   \[
   f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h), \ % \ M
   \]
   such that $f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h) \ % \ M$ with $A_1', \ldots, A_n' \leq \mathcal{B}$;
2. When $f(x_1) + \ldots + f(x_m) = f(y_1) + \ldots + f(y_h), \ % \ M$ with $A_1', \ldots, A_n' \leq \mathcal{B}$, probability that $C_{x_1}, \ldots, C_{x_m}, C_1, \ldots, C_n$ make (4) with $A_1', \ldots, A_n' \leq \mathcal{B}$ hold is roughly $1 / 2^{n-m-h} - 1$.

**Proof:**
It is easy to understand that
\[ W^{(x_1)} = W^{(x_1)^{+\Omega}}, \ldots, W^{(x_n)} = W^{(x_n)^{+\Omega}} (\% M), \]
\[ W^{(y_1)} = W^{(y_1)^{+\Omega}}, \ldots, W^{(y_m)} = W^{(y_m)^{+\Omega}} (\% M), \]
Due to \([W] \neq M, m||W| \neq |h||W|\), and \(\ell(x_1) + \ldots + \ell(x_n) = \ell(y_1) + \ldots + \ell(y_m)\), it follows that
\[ \ell(x_1) + \ldots + \ell(x_n) + m||W| \neq \ell(y_1) + \ldots + \ell(y_m) + |h||W| (\% M). \]

Because \(A_{y_1}, \ldots, A_{y_m}\) need be observed, the constraint \(A_{y_1} \ldots A_{y_m} \leq P^h\) is demanded while because \(A_{x_1}, \ldots, A_{x_n}\) need not be observed, the constraints \(A_{x_1} \leq P, \ldots, A_{x_n} \leq P\) are not demanded.

Let \(\tilde{O}_d\) be an oracle on a discrete logarithm.

Suppose that \(W^r \in [1, M]\) is a generator of \((\mathbb{Z}_M^*, \cdot)\).

Let \(\mu = \ell(y_1) + \ldots + \ell(y_m)\). In terms of group theories, \(\forall A_{y_1}, \ldots, A_{y_m} \in [2, P]\) which need not be pairwise coprime, the equation
\[ C_{y_1} \ldots C_{y_m} = A_{y_1} \ldots A_{y_m} W^\mu (\% M) \]
in \(\mu\) has a solution. \(\mu\) may be obtained through \(\tilde{O}_d\).

\[ \forall \ell(y_1), \ldots, \ell(y_m) \in [1, M], \text{let } \ell'(y_i) = \mu - (\ell(y_1) + \ldots + \ell(y_m)) (\% M). \]

Similarly, \(\forall \ell(x_1), \ldots, \ell(x_m) \in [1, M], \text{let } \ell'(x_m) = \mu - (\ell(x_1) + \ldots + \ell(x_m)) (\% M). \]

Further, from \(C_{x_1} = A'_{x_1} W^\ell(x_1), \ldots, C_{x_m} = A'_{x_m} W^\ell(x_m) (\% M), \) we can obtain a tuple \((A'_{x_1}, \ldots, A'_{x_m})\), where \(A'_{x_1}, \ldots, A'_{x_m} \in [1, M]\), and \(\ell'(x_1) + \ldots + \ell'(x_m) = \ell'(y_1) + \ldots + \ell'(y_m) (\% M). \)

Thus, Property 4.1 is proven.

Let \(G_i = C_{x_1} \ldots C_{x_n}(C_{y_1} \ldots C_{y_m})^{-1} (\% M). \) Then in terms of Property 4.1, there is
\[ C_{x_1} \ldots C_{x_n}(C_{y_1} \ldots C_{y_m})^{-1} = A'_{x_1} \ldots A'_{x_m} W^\ell(x_1)^{+/1} \ldots (\ell(x_m)^{+/1})^{-1} \]
with \(\ell'(x_1) + \ldots + \ell'(x_m) = \ell'(y_1) + \ldots + \ell'(y_m) (\% M). \)

Further, there is
\[ A'_{x_1} \ldots A'_{x_m} = C_{x_1} \ldots C_{x_n}(C_{y_1} \ldots C_{y_m}) = A'_{x_1} \ldots A'_{x_m} W^{\ell(x_1)^{+/1}} \ldots (\ell(x_m)^{+/1})^{-1} (\% M). \]

The above equation manifests that the values of \(W^r\) and \(\ell'(y_1) + \ldots + \ell'(y_m)\) or \(\ell'(x_1) + \ldots + \ell'(x_m)\) do not influence the value of the product \(A'_{x_1} \ldots A'_{x_m}\).

If \(A_{y_1}, \ldots, A_{y_m} \in [2^h, P^h]\) changes, the product \(A_{x_1} \ldots A_{x_m}\) also changes, where \(A_{y_1}, \ldots, A_{y_m}\) is a composite integer. Therefore, \(\forall x_1, \ldots, x_m, y_1, \ldots, y_m \in [1, n]\), the number of potential values of \(A_{x_1} \ldots A_{x_m}\) is roughly \((P^h - 2^h + 1)\).

Let \(M = qP^m(A_{y_1} \ldots A_{y_m})2^{2^h - m - h}\), where \(q\) is a rational number.

According to (3),
\[ G_i/M - L/(A_{y_1} \ldots A_{y_m}) = (A_{x_1} \ldots A_{x_m})/(MA_{y_1} \ldots A_{y_m}) \]
\[ = (A_{x_1} \ldots A_{x_m})/(qP^m2^{2^h - m - h}(A_{y_1} \ldots A_{y_m})^2). \]

When \(A_{x_1} \ldots A_{x_m} \leq qP^m\), there is
\[ G_i/M - L/(A_{y_1} \ldots A_{y_m}) \leq qP^m/(qP^m(A_{y_1} \ldots A_{y_m})2^{2^h - m - h}) \]
\[ = 1/(2^{2^h - m - h}(A_{y_1} \ldots A_{y_m})^2), \]
which satisfies (4).

Assume that the value of \(A_{y_1} \ldots A_{y_m}\) distributes uniformly on the interval \((1, M]\). If \(A_{y_1}, \ldots, A_{y_m}\) is a certain concrete value, the probability that \(A_{x_1} \ldots A_{x_m}\) makes (4) hold at a specific value of \(A_{y_1} \ldots A_{y_m}\) is
\[ qP^m/M = qP^m/(qP^m(A_{y_1} \ldots A_{y_m})2^{2^h - m - h}) \]
\[ = 1/((A_{y_1} \ldots A_{y_m})2^{2^h - m - h}). \]

In fact, it is possible that \(A_{y_1} \ldots A_{y_m}\) take every value in the interval \([2^h, P^h]\) when \(C_{x_1}, \ldots, C_{x_n}, C_{y_1}, \ldots, C_{y_m}\) are fixed. Thus, the probability that \(A_{x_1} \ldots A_{x_m}\) makes (4) hold is
\[ P_{x_1, \ldots, x_m, y_1, \ldots, y_m} = (1/(2^{2^h-m-h}))(1/(2^h + 1) + \ldots + 1/P^h) \]
\[ > (1/(2^{2^h-m-h}))(2(P^h - 2^h + 1)/(P^h + 2^h)) \]
\[ = (P^h - 2^h + 1)/(2^{2^h-m-h}(P^h + 2^h)) \]
\[ \approx 1/2^{2^h-m-h}. \]

Obviously, the larger \(m + h\) is, the larger the probability is, and the smaller \(n\) is, the larger the probability is also.

**Property 5.** Let \(h + m \leq n\). \(\forall x_1, \ldots, x_m, y_1, \ldots, y_m \in [1, n]\), when \(\ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_m)\), the probability that another \(A_i\) makes (4) with \(\tilde{A}_j \leq P^h\) hold is roughly \(1/2^{2^h-m-h-1}\).

**Proof.**

Let
\[ G_i = C_{x_1} \ldots C_{x_m} = (A_{x_1} \ldots A_{x_m}) W^\ell(x_1)^{+/1} \ldots + \ell(x_m)^{+/1} (\% M), \]
Due to \( \ell(x_i) + \ldots + \ell(x_m) = \ell(y_i) + \ldots + \ell(y_h) \), there is
\[ G_z = G_x G_y^{-1} = (A_{y_1} \ldots A_{y_h})(A_{y_1} \ldots A_{y_h})^{-1} = (A_{y_1} \ldots A_{y_h})\bar{A}_y^{-1} \quad (\% \ M). \]

According to the derivation of (4\( \bar{\cdot} \)), \( \bar{A}_y \) will occur in a convergent of the continued fraction of \( G_z / M \).

Let \( p_1 / q_1, \ldots, p_i / q_i < L / \bar{A}_y, p_{i+1} / q_{i+1}, \ldots, p_t / q_t \) be the convergent sequence of the continued fraction of \( G_z / M \), where \( t \leq \lceil \lg M \rceil \).

Because of \( G_z / M - L / \bar{A}_y < 1 / (2^{n-m-h} \bar{A}_y^2) \), it will lead
\[ |G_z / M - p_{i+1} / q_{i+1}| < 1 / (2^{n-m-h} q_{i+1}^2) \quad \text{with} \quad q_{i+1} \leq \mathcal{D}, \]
\[ \ldots \quad \text{or} \]
\[ |G_z / M - p_i / q_i| < 1 / (2^{n-m-h} q_i^2) \quad \text{with} \quad q_i \leq \mathcal{D}, \]
to probably hold, and in terms of Property 4.2, the probability is roughly \( 1 / 2^{n-m-h} \).

Notice that in this case, there is \( \ell'(x_i) + \ldots + \ell'(x_m) = \ell'(y_i) + \ldots + \ell'(y_h) \) with \( A'_{y_1} \ldots A'_{y_h} \leq \mathcal{D} \), where \( \ell'(x_i), \ldots, \ell'(x_m), \ell'(y_i), \ldots, \ell'(y_h) \) satisfy
\[ C_{y_1} = A'_{y_1} W^{\ell(y_1)}, \ldots, C_{y_h} = A'_{y_h} W^{\ell(y_h)}, \quad C_{y_1} = A'_{y_1} W^{\ell(y_1)}, \ldots, C_{y_h} = A'_{y_h} W^{\ell(y_h)} \quad (\% \ M). \]

\[ \bar{A}_y \]

End.

Property 5 illuminates that the nonuniqueness of \( \bar{A}_y \), namely there may exist the disturbance of \( \bar{A}_y \).

The smaller \( m + h \) is, the less the disturbance is.

### 4.2 Some Conditions Are Only Necessary

**Property 6:** (4) is necessary but insufficient for \( \ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_h) \) with \( x_1, \ldots, x_m, y_1, \ldots, y_h \in [1, n] \), namely for the powers of \( W \) and \( W^{-1} \) in \( G_z \) to counteract each other.

**Proof:**

Suppose that \( \ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_h) \).

Let \( \{C_1, \ldots, C_m\} \) be a public key sequence, and \( M \) be a modulus, where \( C_i = A_i W^{\ell(i)} \) \( (\% \ M) \).

Let \( G_x = C_1 \ldots C_m \) \( (\% \ M) \), \( G_y = C_{y_1} \ldots C_{y_h} \) \( (\% \ M) \), and \( G_z = G_x G_y^{-1} \) \( (\% \ M) \).

Further, \( G_z = (A_1 \ldots A_m)(A_{y_1} \ldots A_{y_h})^{-1} \) \( (\% \ M) \).

Denote the product \( A_{y_1} \ldots A_{y_h} \) by \( \bar{A}_y \). Similar to Section 4.1, we have
\[ G_z / M - L / \bar{A}_y < 1 / (2^{n-m-h} \bar{A}_y^2), \]

Namely (4) holds.

**Insufficiency:**

Suppose that (4) holds.

The contrapositive of the proposition that if (4) holds, \( \ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_h) \) holds is that if \( \ell(x_1) + \ldots + \ell(x_m) \neq \ell(y_1) + \ldots + \ell(y_h) \), (4) does not hold.

Hence, we need to prove that when \( \ell(x_1) + \ldots + \ell(x_m) \neq \ell(y_1) + \ldots + \ell(y_h) \), (4) still holds.

In terms of Property 4.2, when \( \ell(x_1) + \ldots + \ell(x_m) \neq \ell(y_1) + \ldots + \ell(y_h) \), the (4) holds with the probability \( 1 / 2^{n-m-h-1} \), which reminds us that when \( \{C_1, \ldots, C_m\} \) is generated, some subsequences in the forms \( \{C_{y_1}, \ldots, C_{y_h}\} \) and \( \{C_{y_1}, \ldots, C_{y_h}\} \) which are verified to satisfy (4) with \( \ell(x_1) + \ldots + \ell(x_m) \neq \ell(y_1) + \ldots + \ell'(y_h) \) can always be found beforehand through adjusting the values of \( W \) and some elements in \( \{A_1, A_2, A_4, A_7, A_i\} \) or \( \{\ell(1), \ell(2), \ell(n)\} \).

Hence, the (4) is not sufficient for \( \ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_h) \).

**Property 7:** (4) is necessary but not sufficient for \( \ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_h) \) with \( x_1, \ldots, x_m, y_1, \ldots, y_h \in [1, n] \), for the powers of \( W \) and \( W^{-1} \) in \( G_z \) to counteract each other.

**Proof:**

Because (4) is derived from (4), and Property 6 holds, naturally Property 7 holds.

**Property 8:** Let \( m = 2 \) and \( h = 1 \). \( \forall x_1, x_2, y_1 \in [1, n] \), when \( \ell(x_1) + \ell(x_2) \neq \ell(y_1) \),

\[ \exists \text{ there always exist} \]
\[ C_{y_1} = A'_{y_1} W^{\ell(y_1)}, \quad C_{y_2} = A'_{y_2} W^{\ell(y_2)}, \quad C_{y_1} = A'_{y_1} W^{\ell(y_1)} \quad (\% \ M), \]

such that \( \ell'(x_1) + \ell'(x_2) = \ell'(y_1) \) \( (\% \ M) \) with \( A'_{y_1} \leq P \).

\[ \exists C_{y_1}, C_{y_2}, C_{y_1} \text{ make } (4) \text{ with } A'_{y_1} \leq P \text{ hold in all probability}. \]

**Proof:**

\[ \text{It is similar to the proving process of Property 4.1.} \]

\[ \text{Let} \]
\[ G_z = C_{y_1} C_{y_2} C_{y_1}^{-1} = A'_{y_1} A'_{y_2} W^{\ell(y_1) + \ell(y_2)} (A'_{y_1} W^{\ell(y_1)})^{-1} \quad (\% \ M) \]

with \( \ell'(x_1) + \ell'(x_2) = \ell'(y_1) \) \( (\% \ M) \).

7
Further, there is $A'_x, A'_y = C_x C_y C^{-1}_{x y} A'_1 (\% M)$.

It is easily seen from the above equations that the values of $W$ and $\ell'(y)$ do not influence the value of $(A'_x, A'_y)$.

If $A'_1 \in [2, P]$ changes, $A'_x, A'_y$ also changes. Thus, for $x_1, x_2, y_1 \in [1, n]$, the number of potential values of $A'_x, A'_y$ is $P - 1$.

Let $M = 2q P^2 A'_1$, where $q$ is a rational number.

According to (3),

$$G_x / M - L / A'_1 = A'_x A'_y / (MA'_1) = A'_x A'_y / (2q P^2 A'_1).$$

When $A'_x A'_y \leq q P^2$, there is

$$G_x / M - L / A'_1 \leq q P^2 / (2q P^2 A'_1)$$

which satisfies (4°).

Assume that the value of $A'_x A'_y$ distributes uniformly on $(1, M)$. Then, the probability that $A'_x A'_y$ makes (4°) hold is

$$P_{x_1, x_2, y_1 \in [1, \ldots, n]} = (q P^2 / (2q P^2)) (1/2 + \ldots + 1 / P)$$

$$\geq (1/2)(2(P - 1)/(P + 2))$$

$$= 1 - 3 \div (P + 2).$$

Apparently, $P_{x_1, x_2, y_1 \in [1, \ldots, n]}$ is very large, and especially when $P$ is pretty large, it is close to 1. □

According to Property 8.2, for a certain $C_y$, and $\forall C_x, C_x \in \{C_1, \ldots, C_n\}$, attack by (4°) will produce roughly $n^2 / 2$ possible values of $A_x$, including the repeated, while attack by (4) may filter out most of the disturbing data of $A_y$. Because every $A_y \leq P < n^2 / 2$ in REESSE1, the number of potential values of $A_y$ is at most $P$ in terms of the pigeonhole principle, which indicates the running time of discriminating the original coprime sequence from the values of $A_x, \ldots$, the values of $A_y$ is $O(P^2)$.

Property 9: (4°) is necessary but not sufficient for $\ell(x_1) + \ell(x_2) = \ell(y)$ with $x_1, x_2, y_1 \in [1, n]$, namely for the powers of $W$ and $W^{-1}$ in $G_x$ to counteract each other.

Proof.

Because (4°) is derived from (4), and Property 6 holds, naturally Property 9 holds. □

It should be noted that Property 2, 3, ..., 9 do not depend on the selection of codomain of the lever function $\ell(.)$, namely regardless of selecting the old $\Omega$ or the new $\Omega_m$, Property 2, 3, ..., 9 still hold.

4.3 Two Discrepant Cases

The cases of $h = 1$ and $h \neq 1$ need to be treated distinguishingly.

4.3.1 Case of $h = 1$: Verification by Examples

The $h = 1$ means that $A'_y = A'_2$. If $A'_y$ is determined, a certain $A'_2$ might be exposed directly. A single $A'_2$ may be either prime or composite, and thus “whether $A'_2$ is prime” may not be regarded as the criterion of the powers of $W$ and $W^{-1}$ counteracting each other.

If take $m = 2$ and $h = 1$, in terms of Property 4.2, the probability $P_{x_1, x_2, y_1 \in [1, n]}$ that $A'_x A'_y$ makes (4°) hold is roughly $1/(2^{n-4} + n)$ and the number of rationals formed as $G_x / M$ which lead (4) to hold is roughly $n^2 / 2^{n-4}$ when the interval $[1, n]$ is traversed by $x_1, x_2, y_1$ separately. Notice that $P_{x_1, x_2, y_1 \in [1, n]}$ is with respect to (4), but not with respect to (4°) or (4°).

Notice that due to $\Omega = \{-/+5, \+'/−6, \ldots, \+'/−(n + 4)\}$, the value of $\ell(x_1) + \ell(x_2) = (−5) + 6 = 1$ for example does not necessarily occur in $\Omega$. In what follows, we validate Property 6 and 8 with two examples when $m = 2$ and $h = 1$. Especially assume that $\Omega_2 = \{5, 6, \ldots, n + 4\}$ is selected to a turn.

Example 1:

It will illustrate the ineffectuality of continued fraction attack by (4).

Assume that the bit-length of a plaintext block is $n = 6$.

Let $A_1 = \{11, 10, 3, 7, 17, 13\}$, and $\Omega_2 = \{5, 6, 7, 8, 9, 10\}$.

Find $M = 510931 > 11 \times 10 \times 3 \times 7 \times 17 \times 13$.

Stochastically pick $W = 17797$, and

$$\ell(1) = 9, \ell(2) = 6, \ell(3) = 10, \ell(4) = 5, \ell(5) = 7, \ell(6) = 8.$$

From $C_1 = A_1 W^{(1)} (\% M)$, we obtain
\[ \{C_i\} = \{113101, 79182, 175066, 433093, 501150, 389033\}. \]

Stochastically pick \( x_1 = 2, x_2 = 6, \) and \( y_1 = 5. \)

Notice that there is \( \ell(5) \neq \ell(2) + \ell(6). \)

Compute
\[
G_2 = C_2 C_6 C_1^{-1} = 79182 \times 389033 \times 433038 = 342114 \times 510931.
\]

Presuppose that the power of \( W \) in \( C_2 C_6 \) is just counteracted by the power of \( W^{-1} \) in \( C_1^{-1} \), and then
\[
342114 = A_2 A_6 A_1^{-1} \times 510931.
\]

According to (3),
\[
342114 / 510931 = L / A_5 = A_2 A_6 / (510931 A_5).
\]

It follows that the continued fraction expansion of \( 342114 / 510931 \) equals
\[
1 / (1 + 1 / (2 + 1 / (37 + 1 / (1 + 1 / (2 + \ldots + 1 / 4)))�),
\]

where the denominators \( 1 = a_1, 2 = a_2, 37 = a_3, \ldots. \)

Heuristically let
\[
L / A_5 = 1 / (1 + 1 / 2) = 2 / 3,
\]

which indicates it is probable that \( A_5 = 3. \)

Further,
\[
342114 / 510931 \times 2 / 3 = 0.002922769 < 1 / (2 \times 3^2) = 0.01388889,
\]

which satisfies (4). Then \( A_5 = 3 \) is deduced, which is in direct contradiction to factual \( A_5 = 17, \) so it is impossible that (4) may serve as a sufficient condition.

Meanwhile, in Example 1, we observe \( a_2 = 2 \) and \( a_1 = 37, \) and the increase from \( a_2 \) to \( a_3 \) should be sharp. However, even though the case is this, the continued fraction attack by (4) fails.

**Example 2:**

It will illustrate the ineffectuality of a continued fraction attack by a discriminant relevant to (4\textsuperscript{r}).

The following Algorithm 4.3.1 which is evolved from the analysis task in [12] describes a continued fraction attack on a simplified REESSE1+ private key. The attack rests on the discriminant
\[
q_n A < q_{n+1} \quad \text{and} \quad q_{n} < A_{\text{max}},
\]

where \( q_n, q_{n+1}, A, \) and \( A_{\text{max}} \) are referred to Algorithm 4.3.1 for their meanings.

In terms of [12], (5) is derived from (4\textsuperscript{r}). Seemingly, (5) is stricter than (4\textsuperscript{r}), and intentionally used uniquely to determine the value of \( A_{\text{bij}}. \)

**Algorithm 4.3.1:**

**INPUT:** a public key \( \{C_1, \ldots, C_b\}, M. \)

S1: Generate the first \( 2n \) primes \( p_1, \ldots, p_{2n} \) of the natural set.

S2: Set \( \Delta \leftarrow (M / (2 \prod_{i=1}^{n} p_i))^{1/2}, A_{\text{max}} \leftarrow M / \prod_{i=1}^{n-1} p_i, \)

where \( n \) meets \( \prod_{i=1}^{n} p_i < M \leq \prod_{i=1}^{n-1} p_i. \)

S3: For \( (x_1 = 1, x_1 \leq n, x_1++) \)

For \( (x_2 = 1, x_2 \leq n, x_2++) \)

For \( (y_1 = 1, y_1 \leq n, y_1++) \) \{ \}

Compute \( G_{x_1 y_1} \leftarrow C_{x_1} C_{y_1} C_{\Delta}^{-1} \% M; \)

Get convergent sequence \( \{r_0/q_0, r_1/q_1, \ldots, r_k/q_k\} \)

of continued fraction of \( G_{x_1 y_1} / M; \)

Get denominator sequence \( \{q_1, q_2, \ldots, q_k\} \)

from the convergent sequence;

For \( (s = 1, s \leq t, s++) \)

If \( (q_s \Delta < q_{s+1}) \) and \( (q_s < A_{\text{max}}) \) then \{

Let \( A_{\text{bij}} \leftarrow q_s; \)

Return \( (A_{\text{bij}}, (x_1, x_2, y_1)). \)

\}

**OUTPUT:** entries \( (A_{\text{bij}}, (x_1, x_2, y_1)). \)

Notice that \( z++ \) denotes \( z \leftarrow z + 1, \) where \( z \) is any arbitrary variable.

However, Algorithm 4.3.1 is ineffectual in practice. Please see the following example.

Assume that the bit-length of a plaintext block is \( n = 10. \)

Let \( \mathcal{A} = \{437, 221, 77, 43, 37, 29, 41, 31, 15, 2\}, \) and \( \mathcal{A}_k = \{5, 6, 7, 8, 9, 10, 11, 12, 13, 14\}. \)

Find \( M = 13082761331670077 > \prod_{a \in A} = 13082761331670030. \)

Randomly select \( W = 944516391, \) and
\[
\ell(1) = 11, \ell(2) = 14, \ell(3) = 13, \ell(4) = 8, \ell(5) = 10, \ell(6) = 5, \ell(7) = 9, \ell(8) = 7, \ell(9) = 12, \ell(10) = 6.
\]
By \( C_i = A_{iW^{(i)}}(\% \ M) \), obtain \\
\{\( C_1, \ldots, C_{10} \)\} = \{3534250731208421, 12235924019299910, 8726060645493642, 10110020851673707, 2328792308267710, 8425476748983036, 6187583147203887, 10200412235916586, 9359330740489342, 5977236088006743\}.

On input the public key \( \{C_i\}, M \), the program (see Appendix A) by Algorithm 4.3.1 will evaluate \( \Delta = 506 \), \( A_{\text{max}} = 58642670 \), and output \( A_y^1 \) and \( (x_1, x_2, y_1) \). Structure Table 1 with entries \( (A_y^1, (x_1, x_2, y_1)) \).

On Table 1, the number of triples \( (x_1, x_2, y_1) \) is greater than 100.

</tbody>
</table>
On Table 1, we observe that

- $A_{i_1}$ relevant to 5 triples is $A_2 = 221$ or $A_3 = 11$,
- $A_{i_1}$ relevant to 4 triples is $A_3 = 77$ or $A_9 = 5$,
- $A_{i_1}$ relevant to 3 triples is $A_1 = 23$, $A_4 = 37$, or $A_9 = 15$,
- $A_{i_1}$ relevant to 2 triples is $A_1 = 77$, $A_2 = 77$, $A_3 = 12$, $A_4 = 56$, $A_5 = 41$, or $A_7 = 3$ etc,
- $A_{i_1}$ relevant to 1 triple is $A_1 = 187125$, $A_2 = 1251$, $A_3 = 121089$, or $A_2 = 4204$.

Among these $A_{i_1}$’s, there exist at least $2^{n-5}$ compatible selections from which some elements of the coprime sequence \{$A_i$\} can be obtained.

For instance, randomly select compatible $A_{i_1}$’s: $A_3 = 11$, $A_6 = 9$, $A_1 = 23$, $A_4 = 41$, and $A_2 = 1251$, and work out $\ell(v_1)$’s: $\ell(3) = 14$, $\ell(9) = 13$, $\ell(1) = 12$, $\ell(5) = 11$, and $\ell(2) = 10$ according to the rule that the number of the triples $(x_1, x_2, y_1)$ tied to $A_{i_1}$ equals $(\ell(v_1) - 9)$ when $\ell(v_1) \geq 10$ [12].

Obviously, such $A_1, A_2, A_3, A_4$ are not original elements, which indicates (5) derived from (4”) is essentially insufficient even if a concrete $\Omega_2 = \{5, \ldots, n + 4\}$ is selected and known.

### 4.3.2 Case of $h \neq 1$

The $h \neq 1$ means $\tilde{A}_i = A_{i_1}, \ldots, A_{i_9}$. It is well known that any composite $\tilde{A}_i \neq p^k$ ($p$ is a prime) can be factorized into some prime multiplicative factors, and many coprime sequences of the same length can be obtained from a prime factor set.

For instance, let $h = 3$ and $A_i = 210$ with the prime factor set \{2, 3, 5, 7\}. We can obtain the coprime sequences \{5, 6, 7\}, \{6, 5, 7\}, \{3, 7, 10\}, \{10, 3, 7\}, \{2, 15, 7\}, \{3, 2, 35\}, etc. Which is the original?

Property 4 makes it clear that due to the indeterminacy of $\ell(.)$, no matter whether the power of $W$ and $W^{-1}$ counteract each other or not, in some cases, one or several values of $\tilde{A}_i$ which may be written as the product of $h$ coprime integers, and satisfy (4) can be found out from the convergents of the continued fraction of $G_M$ when the interval $[1, n]$ is traversed respectively by $x_1, \ldots, x_m, y_1, \ldots, y_k$.

Thus, “whether $\tilde{A}_i$ can be written as the product of $h$ coprime integers” may not be regarded as a criterion for verifying that the powers of $W$ and $W^{-1}$ counteract each other.

Moreover, even if the $k$ values $v_1, \ldots, v_k$ of the product $A_{i_1}A_{i_2}\ldots A_{i_k}$ are obtained, where $y_1$ is fixed, and $y_2, \ldots, y_k$ are varied, $\gcd(v_1, \ldots, v_k)$ cannot be judged to be $A_{i_1}$ in terms of the definition of a coprime sequence.

If take $m = 2$ and $h = 2$, in terms of Property 4.2 and $P^{v_1, x_2, y_1, y_2} \in [1, n]$ the number of rationals formed as $G_M$ which leads (4) to hold is roughly $n^2/2^{n-5}$ when the interval $[1, n]$ is traversed by $x_1, x_2, y_1, y_2$ respectively. What is most pivotal is that the value of $\ell(x_1) + \ell(x_2)$ or $\ell(y_1) + \ell(y_2)$ $\forall x_1, x_2, y_1, y_2 \in [1, n]$ does not necessarily occur in a concrete $\Omega_2$.

### 4.4 Time Complexities of Two Attack Tasks

Continued fraction attack and parameter intersection attack on $C_i = A_i M^{[0]}$ ($\%M$) are the two most efficient algorithms at present.

#### 4.4.1 Time Complexity of Continued Fraction Attack

It can be seen from section 4.1 that continued fraction attack is based on the assumption that $\ell(x_1) + \ldots + \ell(x_m) = \ell(y_1) + \ldots + \ell(y_k)$. For convenience, usually let $m = 2$ and $h = 1$.

If $\Omega_2$ is determined as \{5, \ldots, $n + 4$\}, continued fraction attack by (4), (4’), (4") or (5) contains five steps dominantly.

Note that it is known from Example 2 that $\Omega_2 = \{5, \ldots, n + 4\}$ does not mean that continued fraction attack will succeed.

Algorithm 4.4.1:

**INPUT**: a public key \{\{C_1, \ldots, C_A\}, M\};
- the set $\Omega_2 = \{5, \ldots, n + 4\}$.

**S1**: Structure Table 2 according to $\Omega_2$.

**S2**: Get entries $(A_{i_1}, (x_1, x_2, y_1))$ by calling Algorithm 4.3.1.
S3: Structure Table 1 with entries \((A_{y_1}, (x_1, x_2, y_1))\).
S4: Find coprime \(A_{y_1}\) according to Table 1 and Table 2.
S5: Find pairwise different \(\ell(y_1)\) according to \(A_{y_1}\) and Table 2.

<table>
<thead>
<tr>
<th>(\ell(y_1))</th>
<th>10</th>
<th>11</th>
<th>\ldots</th>
<th>(n + 4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\ell(x_1) + \ell(x_2))</td>
<td>5 + 5</td>
<td>5 + 6</td>
<td>\ldots</td>
<td>5 + (n - 1), \ldots, (n - 1) + 5</td>
</tr>
<tr>
<td>Number of (\ell(y_1) = \ell(x_1) + \ell(x_2))</td>
<td>1</td>
<td>2</td>
<td>\ldots</td>
<td>(n - 5)</td>
</tr>
</tbody>
</table>

Table 2: Number of \(\ell(x_1) + \ell(x_2) = \ell(y_1)\) over \(\Omega_2 = \{5, \ldots, n + 4\}\)

At S4, finding coprime values of \(A_{y_1}\) will probably take \(O(2^{n-5})\) running time.

At S1, when \(\Omega_2\) is indeterminate (in fact, \(\Omega_2\) is one of \(2^n\) potential sets), an adversary must firstly determine all the elements of \(\Omega_2\), which will take \(O(2^n)\) running time.

4.4.2 Time Complexity of Parameter Intersection Attack

Due to \(C_i = A_i W^{(i)}(\% M)\) with \(A_i \in A = \{2, \ldots, P\}\) and \(\ell(i) \in \Omega_2 = \{+/-5, \ldots, +/-(n + 4)\}\) for \(i = 1, \ldots, n\), and elements in the sets \(A\) and \(\Omega_2\) being small, an adversary may attempt the following attack with indeterminacy.

Algorithm 4.4.2:

- **INPUT:** a public key \((\{C_1, \ldots, C_n\}, M)\); the set \(A\).
- **S1:** For \(i = 1, \ldots, n\) do
  - while \(\ell(i)\) traverses \{5, \ldots, \(n + 4\), -5, \ldots, -(n + 4)\} do
    - while \(A_i\) traverses \(A\) do
      - **S1.1:** compute \(W = C_i A^{-1} (\% M)\);
      - **S1.2:** place the triple \((W, A_i, \ell(i))\) into the set \(V_i\).
- **S2:** Seek the intersection \(V = V_1 \cap \ldots \cap V_n\) on \(W\).
- **S3:** If \(W\) unique in \(V\), and related \((A_i, \ell(i))\) unique in every \(V_i\) then
  - a private key \((\{A_i\}, \{\ell(i)\}, W)\) is extracted
  - else (namely \(W\) nonunique in \(V\) or \((A_i, \ell(i))\) nonunique in some \(V_i\)'s)
    - check whether every possible \(\{A_i, \ldots, A_n\}\) is a coprime sequence, and whether every possible \(\{\ell(1), \ldots, \ell(n)\}\) is a lever function.
- **S4:** make a list of valid \((\{A_i\}, \{\ell(i)\}, W)\).
- **OUTPUT:** the list of a private key \((\{A_i\}, \{\ell(i)\}, W)\).

When the number of private keys is larger than 1, the original private key need to be verified.

Note that at S1.1, may compute \(W\) by the Moldovyan root finding method [13], and the time complexity of the method is \(O((\ell(i))^{1/2}|\lg M|) = O(n^{1/2}|\lg M|)\).

The size of every \(V_i\) is about \(O(|A_i|\Omega_2^2)|\equiv q^2|\mathcal{M}\) prime \(q \in |\Omega_2|\).

At S2, seeking the intersection \(V\) will take \(O(Pn^2)\) running time which is polynomial in \(n\).

At S3, seeking a coprime sequence will take \(O(n)\) running time in the best case with pretty low probability due to \(q_2^2|\mathcal{M}\) prime \(q \in |\Omega_2|\), but it will take \(O(2^n)\) running time in a worse case.

Thus, the adversary cannot extract a simplified REESSE1+ private key in deterministic polynomial time.

5 Relation between a Lever Function and a Random Oracle

5.1 What Is a Random Oracle

An oracle is a mathematical abstraction, a theoretical black box, or a subroutine of which the running time may not be considered [11][14]. In particular, in cryptography, an oracle may be treated as a subcomponent of an adversary, and lives its own life independent of the adversary. Usually, the adversary interacts with the oracle but cannot control its behavior.

A random oracle is an oracle which answers to every query with a completely random and unpredictable value chosen uniformly from its output domain, except that for any specific query, it outputs the same value every time it receives that query if it is supposed to simulate a deterministic function [14].

Random oracles are utilized in cryptographic proofs for replacing any irrealizable function so far which can provide the mathematical properties required by the proof. A cryprosystem or a protocol that
is proven secure using such a proof is described as being secure in the random oracle model, as opposed to being secure in the standard model where the integer factorization problem, the discrete logarithm problem etc are assumed to be hard. When a random oracle is used within a security proof, it is made available to all participants, including adversaries. In practice, random oracles producing a bit-string of infinite length which can be truncated to the length desired are typically used to model cryptographic hash functions in schemes where strong randomness assumptions of a hash function’s output are needed.

In fact, it draws attention that certain artificial signature and encryption schemes are proven secure in the random oracle model, but are trivially insecure when any real hash function such as MD5 or SHA-1 is substituted for the random oracle [15][16]. Nevertheless, for any more natural protocol, a proof of security in the random oracle model gives very strong evidence that an attacker have to discover some unknown and undesirable property of the hash function used in the protocol.

A function or algorithm is regarded random if its output depends not only on the input but also on some random ingredients, namely if its output is not uniquely determined by the input. Hence, to a function or algorithm, randomness contains indeterminacy.

### 5.2 Design of a Random Oracle

Correspondingly, the indeterminacy of the $\ell(i)$ may be expounded in terms of a random oracle.

Suppose that $O_d(x, y)$ is an oracle on solving $y = g^x \pmod M$ for $x$, and $O_i$ is an oracle on solving $C_i = A_iW^{i(0)} \pmod M$ for $\ell(i)$, where $M$ is prime, and $i$ is from 1 to $n$.

Let $D$ be a database which stores records $\{(C_i, ..., C_n), M, \{\ell(1), ..., \ell(n)\}\}$ computed already. If the arrangement order of some $C_i$’s is changed, $\{C_i, ..., C_n\}$ is regarded as a distinct sequence.

The structure of $O_i$ is as Algorithm 4.5.2:

**INPUT:** a public key $\{(C_i, ..., C_n), M\}$.

**INPUT:** a public key $\{(C_i, ..., C_n), M\}$.

1. If find $\{(C_i, ..., C_n), M\}$ in $D$ then
   - retrieve $\{(\ell(1), ..., \ell(n))\}$, goto S6.

2. Randomly produce a coprime sequence $A_1, ..., A_n$
   - with each $A_i \in \mathcal{P}$ and $\prod_{i=1}^n A_i < M$.

3. Randomly pick a generator $W \in \mathbb{Z}_M^\ast$.

4. Evaluate $\ell(i)$ by calling $O_d(C_iA_i^{-1}, W)$ for $i = 1, ..., n$.

5. Store $\{(C_i, ..., C_n), M, \{\ell(1), ..., \ell(n)\}\}$ to $D$.

6. Return $\{(\ell(1), ..., \ell(n))\}$, and end.

**OUTPUT:** a sequence $\{(\ell(1), ..., \ell(n))\}$.

Of course, $\{A_i\}$ and $W$ as side results may be outputted.

Obviously, for the same input $\{(C_i, ..., C_n), M\}$, the output is the same, and for a different input, a related output is random and unpredictable.

Since $C_iA_i^{-1}$ is pairwise distinct, and $W$ is a generator, the result $\{(\ell(1), ..., \ell(n))\}$ will be pairwise distinct. Again according to Definition 2, every $\ell(i) \in [1, M]$ may be beyond $\Omega_e$. Thus, $\{(\ell(1), ..., \ell(n))\}$ is a lever function although it is not necessarily the original.

The $O_i$ is perhaps strange to some people because they have never met any analogous oracle in classical cryptosystems.

Section 5 explains further why the continued fraction attack by (4), (4″), (4′), or (5) and parameter intersection attack is ineffectual on $C_i = A_iW^{i(0)} \pmod M$.

### 6 Conclusion

Indeterminacy is ubiquitous. For example, for $x + y = z$, given $x = -122$ and $y = 611$, computing $z = 489$ is easy, and contrarily, given $z = 489$, seeking the original $x$ and $y$ is intractable since there exists indeterminacy in $x + y = z$. Indeterminacy in $C_i = A_iW^{i(0)} \pmod M$ is similar, and triggered by the lever function $\ell(.)$.

Inequation (4) is stricter than (4″) although both (4) and (4″) are only necessary but insufficient for $\ell(x_1) + \ell(x_2) = \ell(y)$. Property 4 and 8 show that attack by (4) is more effectual than attack by (4″) theoretically. However, Section 4.3 shows that when $\Omega_e = \{+/-5, ..., +/-(n + 4)\}$ is indeterminate, continued fraction attack by (4), (4″), (4′), or (5) will take $O(2^n)$ running time, and is practically infeasible.

Section 4.4.2 manifests that parameter intersection attack cannot extract a private key in determinate
polynomial time although it unveils some lowly probabilistic risk.

Therefore, the new lever function $\ell(.)$ from $\{1, \ldots, n\}$ to $\{+/−5, \ldots, +/−(n + 4)\}$ is necessary and sufficient for resisting continued fraction attack and parameter intersection attack.

Resorting to $C_i = A_i W^{\ell(i)} \pmod M$, we expound theoretically the effect of the lever function with indeterminacy. In practice, determinately to assure the security of a private key and to decrease the modulus length of the cryptoscheme, the key transform should be strengthened to $C_i = (A_i W^{\ell(i)})^\delta \pmod M$ with $\delta \in [2, \mathcal{M}]$, $A_i \in \Lambda = \{2, \ldots, \mathcal{P}\}$, and $\ell(i) \in \Omega_\pm = \{+/−5, \ldots, +/−(n + 4)\}$ for $i = 1, \ldots, n$.[6][17].
