**Abstract.** We present RAPTOR, the first practical lattice-based (linkable) ring signature scheme with implementation. RAPTOR is as fast as classical solutions; while the size of the signature is roughly 1.3 KB per user. Prior to our work, all existing lattice-based solutions are analogues of their discrete-log or pairing-based counterparts. We develop a generic construction of (linkable) ring signatures based on the well-known generic construction from Rivest et al., which is not fully compatible with lattices. We show that our generic construction is provably secure in random oracle model. We also give instantiations from both standard lattice, as a proof of concept, and NTRU lattice, as an efficient instantiation. We showed that the latter construction, called RAPTOR, is almost as efficient as the classical RST ring signatures and thus may be of practical interest.

## 1 Introduction

The notion of ring signatures was put forth by Rivest, Shamir and Tauman in 2001 [49]. It is a special type of group signature [18, 16] where a signer is able to produce a signature on behalf of a group of potential signers. Unlike group signatures, there is no central party to manage group membership nor capable of revealing identity of the generator of the signature. In a typical use case of ring signatures, each user is associated with a public key and a group is formed spontaneously by collecting users' public keys. It is a very attractive property as it enables anonymity: the signer hides its identity within the group, and there is no trusted third party that is capable of revocation.

Ring signatures offers very strong anonymity. In particular, signatures created by the same signer are unlinkable. Observing that in some real-world applications, such as electronic voting, unlinkability can be undesirable, Liu, Wei and Wong [39] put forth the notion of linkable ring signatures. In such a scheme, the identity of the signer remains anonymous. In the meantime, two signatures created by the same signer can be linked.

The properties of linkability and signer anonymity are very desirable in various real world applications, including, but not limited to, e-cash, e-voting, and ad-hoc authentication. For example, in the e-cash scenario, a linkable ring signature allows the spender to remain anonymous, while making it possible for the

bank to identify double spenders. To date, linkable ring signature has become a mainstream solution to protect sender privacy in cryptocurrency transaction [46].

All linkable ring signatures deployed in practice are based on number-theoretic assumptions and thus vulnerable to quantum computers [50]. Even though quantum computers are still in their infancy, many believed that general purpose quantum computers will inevitably arrive, by when the exiting classical ring signatures will lose their anonymity and/or unforgeability.

Lattice-based cryptography is one of the most promising families of candidates [45] to the quantum apocalypse. Besides resistance to quantum attacks, problems in lattice-based cryptography exhibits an additional properties, namely, breaking a random instance of a lattice problem is as hard as solving the worst-case instance.

To date, there exist a number of lattice-based ring signature schemes and lattice-based linkable ring signature schemes [15, 43, 37, 26, 53, 11]. While some of them are asymptotically efficient, they are hardly practical. In particular, to the best of our knowledge, none of these constructions come with an implementation.

## 1.1 Related Work

*Classical ring signatures* We review the existing constructions of (linkable) ring signatures. The generic construction introduced by Rivest, Shamir and Tauman [49] in 2001 (RST). This generic construction is based on one-way trapdoor permutations along with a block cipher. It can be instantiated from the RSA assumption. In 2004, Abe, Ohkubo and Suzuku [1] (AOS) proposed a new generic construction which allows discrete-log type of keys. This generic construction can make use of hash-and-sign signature or any three-move sigma-protocol-based signature. It can be instantiated from RSA or discrete-log assumptions. Both of the RST and AOS constructions are secure in the random oracle model and the signature sizes are linear to the ring size. To achieve the security in standard model, Bender, Katz and Morselli [12] (BKM) presented a ring signature scheme which adopts a public-key encryption scheme, a signature scheme and a ZAP protocol for any language in  $\mathcal{NP}$  [25]. Even though BKM construction is secure in standard model, the signature size is still linear in the number of group members and the generic ZAPs are actually quite impractical. Shacham and Waters [?] then proposed a more efficient linear-size ring signature scheme without random oracle from bilinear pairing.

To reduce the signature size, Dodis et al. proposed the first ring signature scheme with constant signature size in 2004 [20]. It relies on accumulator with one-way domain and is secure in the random oracle model. The first ring signature with sub-linear without random oracle model is due to Chandran, Groth and Sahai [17]. This scheme has signature size  $\mathcal{O}(\sqrt{\ell})$  where  $\ell$  is the number of users in the ring. All of the above sub-linear size constructions are secure in the common reference string model that requires a trusted setup. The first sub-linear ring signatures without relying on a trusted setup is due to Groth and

Kohlweiss [30]. It features logarithmic size signature and is secure in the random oracle model.

*Classical linkable ring signatures* Since the first proposal of linkable ring signature [39], we have seen a sequence of work [55, 7, 38, 52] that provides different features. In 2005, Tsang and Wei [55] extends the generic ring signature introduced by Dodis et al. [20] to a linkable version, which also feature constant signature size and is secure in the random oracle model. Au et al. [7] presented a new security model for linkable ring signatures and a new short linkable ring signature scheme that is secure in this strengthened model. In 2014, Liu et al. [38] presented the first linkable ring signature scheme achieving unconditional anonymity. Sun et al. [52] proposed a new generic linkable ring signature to construct RingCT 2.0 for Monero. There are also schemes with special properties such as identity-based linkable ring signatures [54, 9] and certificate-based linkable ring signatures [8].

*Lattice-based ring signatures* For ring signatures in the lattice setting, Brakerski and Kalai [15] proposed a generic ring signature scheme in the standard model. This generic construction is based on a new primitive called ring trapdoor functions. They instantiated this function based on the inhomogeneous short integer solution problem (ISIS). However, the resulting scheme is only secure under a weak definition. To achieve full security, an inefficient transformation is needed. Melchor et al. [43] transforms Lyubashevsky’s lattice-based signature [41] into a ring signature. As the authors pointed out themselves, their scheme is “pretty unpractical”. In 2016, Libert et al. [37] presented a lattice-based accumulator. With the accumulator and a lattice-based zero-knowledge proof system, they build a ring signature scheme that features logarithmic signature size. However, the zero-knowledge arguments applied in the accumulator is very inefficient. The state-of-the-art is the lattice-based ring signature scheme proposed by Es-gin et al. [26]. They adapt the efficient one-out-of-many proof [30, 14] to build a lattice-based ring signature scheme. Same as [37], [26] is also a logarithmic size ring signature scheme and is secure in the random oracle model.

*Lattice-based linkable ring signatures* The first lattice-based linkable ring signature scheme was proposed by Torres et al. in 2018 [53]. It can be seen and instantiation of the AOS framework from the lattice-based BLISS signature [21], with adaption to introduce linkability. The signature size is linear to the number of members in the ring and is reported to be 51 KB per ring member. In the same year, Baum, Lin and Oechsner [11] construct another lattice-based linkable ring signature scheme following a very similar ideal to [53]. The signature size for [11] is claimed to be around 10.3KB per user. The main difference between these two work is the way to achieve linkability. We are not aware of any implementation of these work.

For the existing lattice-based (linkable) ring signature schemes, we are not aware of these constructions come with any implementation. In terms of performance, lattice-based (linkable) ring signatures [43, 53, 11] are all based on the

lattice-based sigma-protocol-based signature and thus involve additional overhead in the form of rejection sampling which affects the performance of the signature scheme. As mentioned above, the inefficiency of the underlying zero-knowledge proof system makes [37] quite impractical. In this paper, we not only present a practical and efficient lattice-based (linkable) ring signature scheme but also implement it on a typical laptop and provide the performance.

## 1.2 Our Contribution

**Table 1.** Performance

(a) RAPTOR-512				(b) Linkable RAPTOR-512

Signature	6.3 KB	12.7 KB	63.3 KB	Signature	7.8 KB	14.2 KB	64.8 KB

We present RAPTOR, the first lattice-based (linkable) ring signature with implementation. It gets its name as it is the next generation of FALCON [27] that features a “stealth” mode. RAPTOR is secure in the random oracle model, based on some widely-accepted lattice assumptions. We also present a less efficient version that is based on standard lattice problems. We implement RAPTOR, and its performance on a typical laptop is shown in Table 1(a) and 1(b). The experimental setting is presented in Section 5.

Our solution is in a sense optimal for the family of solutions where the signatures are linear in terms of users: in our construction, the signature consists of a lattice vector and a random nonce of  $2\lambda$  bits per user. It is unlikely that one is able to reduce the size further within the linear domain. We believe that the only way to get substantially better performance than RAPTOR is from the family of solutions that are logarithmic/constant in the number of users. The best theoretical work in linear size is due to [11], where the signature size is claimed to be 82.5KB with a ring size of 8. Comparing with the state-of-the-art [26] with sublinear signature size, our work is still comparing favourably for ring signature size  $\lesssim 1000$ . As a remark, a common use case of linkable ring signature, privacy protection for cryptocurrency, often uses a ring size less than 20 and thus Raptor is more preferable in this setting. The signature size of [26] is reported to be 930KB with  $2^6$  users in the ring and 1409KB with  $2^{10}$  users in the ring. The comparison of signature size of our RAPTOR and other existing lattice-based (linkable) ring signature scheme is shown in Table 2.

**Table 2.** Comparison of lattice-based (linkable) ring signature at security level  $\lambda = 100$ . Signature size increases with ring size (i.e. number of public keys in the ring).

	[37]	[53]	[11]	[26]	RAPTOR	(linkable) RAPTOR
Signature size growth	logarithm	linear	linear	logarithm	linear	linear
linkability	×	✓	✓	×	×	✓
Implementation	×	×	×	×	✓	✓
Signature size with $2^6$ users	$\approx 37$ MB	$\approx 649$ KB	$\approx 585$ KB	930 KB	80.6 KB	82.7 KB
with $2^8$ users	$\approx 48.1$ MB	$\approx 2474$ KB	$\approx 2340$ KB	1132 KB	332.6 KB	326.5 KB
with $2^{10}$ users	$\approx 59.1$ MB	$\approx 9770$ KB	$\approx 9360$ KB	1409 KB	1290.2 KB	1301.9KB
with $2^{12}$ users	$\approx 70.2$ MB	$\approx 39$ MB	$\approx 37.4$ MB	1492 KB	5161 KB	5203.3 KB

In terms of security, (linkable) RAPTOR is backed by a new generic framework that is provably secure in the random oracle model, under the assumption based on RST construction. Instead of relying on one-way trapdoor permutation, the new generic framework is based on a new primitive called Chameleon Hash Plus ( $\text{CH}^+$ ) which can be instantiated from lattice setting (e.g. NTRU). Our generic construction can additionally transform any ring signature into a one-time linkable ring signature.

Nonetheless, when  $\text{CH}^+$  is instantiated with a standard lattice problem (i.e., the short integer solution problem), we base the security of (linkable) ring signature on the worst-case lattice problems that are conjectured to be hard against quantum computers.

In practice, one often resorts to NTRU lattices [34] for better efficiency. Our (linkable) RAPTOR scheme is such a case, where the  $\text{CH}^+$  function is instantiated from the pre-image samplable function of FALCON [27].

### 1.3 Overview of Our Construction

Before presenting a high-level description of our construction, we first discuss the subtlety of instantiating the RST generic construction from lattices. Recall that the building block of RST ring signatures is one-way trapdoor permutation. While trapdoor functions can be built from lattices, they are not permutations by themselves and therefore cannot be applied directly. Consequently, all existing linear-size lattice-based constructions opt for the AOS framework, which can be built from any sigma-protocol based signatures. Indeed, [53, 11] can be seen as instantiations from this framework. On the other hand, we identify essential properties required by the underlying building blocks in the RST framework. The result is a type of trapdoor function that we called Chameleon hash plus ( $\text{CH}^+$ ), a construct that is similar to Chameleon hash functions.

*Building block:*  $\text{CH}^+$  The main building block for our generic constructions is a chameleon hash plus ( $\text{CH}^+$ ) function. We recall the notion of chameleon hash function which was first formalized by Krawczyk and Rabin in 2000 [35]. Chameleon hash functions are randomized collision-resistant hash functions with an additional property that each hash key is equipped with a trapdoor. With

the trapdoor, one can easily find collisions for any input. More specifically, on input a trapdoor  $\text{tr}$  corresponding to some chameleon hash key  $\text{hk}$ , two messages  $m, m'$  and a randomness  $r$ , one can efficiently compute another randomness  $r'$  such that  $\text{Hash}(\text{hk}, m, r) = \text{Hash}(\text{hk}, m', r')$ .

Our  $\text{CH}^+$  consists of four algorithms, namely, **SetUp**, **TrapGen**, **Hash** and **Inv**. See Section 3.1 for details. Similar to a chameleon hash, without the trapdoor,  $\text{CH}^+$  needs to be one-way and collision-resistant. There are two main difference in  $\text{CH}^+$ :

- to compute new randomness  $r'$  for any given message  $m'$ , only the hash value,  $C = \text{Hash}(\text{hk}, m, r)$ , is needed; whereas both the original message  $m$  and randomness  $r$  are required in a classical Chameleon hash;
- optionally, there exists a system parameter  $\text{param}^{\text{ch}}$  as an implicit input to all  $\text{CH}^+$  operations.

*Our Generic Construction of Ring Signatures* We describe how we can build a ring signature from  $\text{CH}^+$ . We assume  $\text{param}^{\text{ch}}$  is available at the setup. In the key generation procedure, a signer runs algorithm **TrapGen** to obtain hash key  $\text{hk}$  and its trapdoor  $\text{tr}$ . Signer’s public key and secret key will be  $\text{hk}$  and  $\text{tr}$ , respectively.

Suppose a signer,  $S_\pi$ , with public and secret keys  $(\text{hk}_\pi, \text{sk}_\pi)$ , tries to sign message  $\mu$  on behalf of a group of signer  $\{S_1, \dots, S_\ell\}$  ( $\pi \in \{1, \dots, \ell\}$ ),  $S_\pi$  first collects all the public keys of the group of signers  $\{\text{hk}_1, \dots, \text{hk}_\ell\}$ . Next,

- for  $i \neq \pi$ ,  $S_\pi$  randomly samples message  $m_i$ , randomness  $r_i$  and computes hash output  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ ;
- for  $i = \pi$ , i.e., the signer himself,  $S_\pi$  samples a  $C_\pi$ .

$S_\pi$  further sets  $C^* = \mathcal{H}(\mu, C_1, \dots, C_\ell, \text{hk}_1, \dots, \text{hk}_\ell)$  where  $\mu$  is the message to be signed and  $\mathcal{H}$  is a collision-resistant hash function. It then computes  $m_\pi$  which satisfies  $m_1 \oplus \dots \oplus m_\ell = C^*$  and uses the trapdoor to find an  $r_\pi$  such that  $c_\pi = \text{Hash}(\text{hk}_\pi, m_\pi, r_\pi)$ . The signature for  $S_\pi$  on  $\mu$  is  $\{(m_1, r_1), \dots, (m_\ell, r_\ell)\}$ . Note that without the trapdoor, it is hard to find such a randomness  $r_\pi$  since  $\text{CH}^+$  is one-way and collision-resistant.

To verify the signature, one can first compute  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$  for  $i = 1, \dots, \ell$ . Then check whether  $m_1 \oplus \dots \oplus m_\ell$  is equivalent to  $\mathcal{H}(\mu, C_1, \dots, C_\ell, \text{hk}_1, \dots, \text{hk}_\ell)$ . If so, the verifier accepts the signature as signed by one of the group members.

*Our Generic Construction of Linkable Ring Signatures* Linkable ring signature scheme allows others to link two signatures sharing the same signer. At a high level, we will use a tag to achieve this property. The tag is a representative of the signer’s identity for each signature. Signatures that share a same tag are linked. It is natural to enforce that each signer only obtains one unique tag; and this tag cannot be forged, or transferred from/to another user. We use a one-time signature<sup>3</sup> to achieve those properties.

<sup>3</sup> Here we will only use the public key once; the actual signature scheme does not necessarily need to be a one-time signature scheme.

During the key generation procedure, in addition to a  $\text{hk}$  and its trapdoor  $\text{tr}$ , the signer also generates a pair of public key and secret key  $(\text{opk}, \text{osk})$  for a one-time signature. The signer then masks  $\text{hk}$  by  $\mathcal{H}(\text{opk})$  and obtains a masked hash key  $\text{hk}'$ . The unique tag for the signer will be the public key  $\text{opk}$ . In the end, the signer sets  $\text{hk}'$  as public key and  $(\text{tr}, \text{opk}, \text{osk})$  as secret key.

When the signer  $S_\pi$  signs a message  $\mu$  on behalf of a group of signers  $\{S_1, \dots, S_\ell\}$  ( $\pi \in \{1, \dots, \ell\}$ ), it will collect the public keys of the group  $\{\text{hk}'_1, \dots, \text{hk}'_\ell\}$  as usual. For each public key  $\text{hk}'_i$  in the group,  $S_\pi$  computes  $\text{hk}''_i = \text{hk}'_i \oplus \mathcal{H}(\text{opk})$ . A new list of “public keys”,  $\{\text{hk}''_1, \dots, \text{hk}''_\ell\}$ , is then formed. Note that  $\text{hk}''_\pi$  is equivalent to the original  $\text{hk}_\pi$ . Next, the signer  $S_\pi$  invokes the (none linkable) ring signature with keys  $\{\text{hk}''_1, \dots, \text{hk}''_\ell\}$ , a trapdoor  $\text{tr}_\pi$  and a message  $\mu$ , and obtains a (none linkable) ring signature  $\sigma_R = \{(m_1, r_1), \dots, (m_\ell, r_\ell)\}$  on  $\mu$ . Finally,  $S_\pi$  signs  $\mu, \sigma_R$  using  $\text{osk}_\pi$  and gets a one-time signature  $\text{sig}$ . The linkable ring signature produced by  $S_\pi$  will be  $\{\sigma_R, \text{opk}_\pi, \text{sig}\}$ .

As for verification, in addition to verifying  $\sigma_R$ , one should also check whether  $\text{sig}$  is a valid signature on  $\mu$  and  $\sigma_R$  under  $\text{opk}_\pi$ .

## 2 Preliminary

### 2.1 Notation

Elements in  $\mathbb{Z}_q$  are represented by integers in  $[-\frac{q}{2}, \frac{q}{2})$ . For a ring  $\mathcal{R}$  we define  $\mathcal{R}_q$  to be the quotient ring  $\mathbb{Z}_q[x]/(x^n + 1)$  with  $n$  being a power of 2 and  $q$  being a prime. Column vectors in  $\mathbb{Z}_q^n$  and elements in  $\mathcal{R}_q$  are denoted by lower-case bold letters (e.g.  $\mathbf{x}$ ). Matrices are denoted by upper-case bold letters (e.g.  $\mathbf{X}$ ). We use  $\hat{\mathbf{x}}$  to denote a column vector with entries from the ring.

For distribution  $D$ ,  $x \leftarrow_{\S} D$  means sampling  $x$  according to distribution  $D$ .  $\|\mathbf{v}\|_1$  is the  $\ell_1$  norm of vector  $\mathbf{v}$  and  $\|\mathbf{v}\|$  is the  $\ell_2$  norm of  $\mathbf{v}$ . For  $\hat{\mathbf{v}} = (\mathbf{v}_1, \dots, \mathbf{v}_n)^T$ , we define  $\|\hat{\mathbf{v}}\| = \sqrt{\sum_{i=1}^n \|\mathbf{v}_i\|^2}$ .

The continuous normal distribution over  $\mathbb{R}^n$  centered at  $\mathbf{v}$  with standard deviation  $\sigma$  is defined as  $\rho_{\mathbf{v}, \sigma}^n(\mathbf{x}) = (\frac{1}{\sqrt{2\pi\sigma^2}})^n e^{-\frac{\|\mathbf{x}-\mathbf{v}\|^2}{2\sigma^2}}$ . For simplicity, when  $\mathbf{v}$  is the zero vector, we use  $\rho_{\sigma}^n(\mathbf{x})$ .

The discrete normal distribution over  $\mathbb{Z}^n$  centered at  $\mathbf{v} \in \mathbb{Z}^n$  with standard deviation  $\sigma$  is defined as  $D_{\mathbf{v}, \sigma}^n(\mathbf{x}) = \frac{\rho_{\mathbf{v}, \sigma}^n(\mathbf{x})}{\rho_{\sigma}^n(\mathbb{Z}^n)}$ .

We define the exclusive-or operation of two matrix  $\mathbf{X}^{(1)} \in \mathbb{Z}_q^{n \times m}$  and  $\mathbf{X}^{(2)} \in \mathbb{Z}_q^{n \times m}$ ,  $\mathbf{X}^{(1)} \oplus \mathbf{X}^{(2)}$ , as:

$$\begin{bmatrix} \mathbf{b}_q(x_{11}^{(1)}) \oplus \mathbf{b}_q(x_{11}^{(2)}) & \dots & \mathbf{b}_q(x_{1m}^{(1)}) \oplus \mathbf{b}_q(x_{1m}^{(2)}) \\ \vdots & \ddots & \vdots \\ \mathbf{b}_q(x_{n1}^{(1)}) \oplus \mathbf{b}_q(x_{n1}^{(2)}) & \dots & \mathbf{b}_q(x_{nm}^{(1)}) \oplus \mathbf{b}_q(x_{nm}^{(2)}) \end{bmatrix}$$

where  $\mathbf{b}_q(x)$  means that transform a value  $x \in \mathbb{Z}_q$  to its binary representation.  $\mathbf{b}_q(\cdot)$  can be efficiently computed.

## 2.2 Lattices and Hardness Assumptions

A lattice in  $m$ -dimension Euclidean space  $\mathbb{R}^m$  is a discrete set

$$\Lambda(\mathbf{b}_1, \dots, \mathbf{b}_n) = \left\{ \sum_{i=1}^n x_i \mathbf{b}_i \mid x_i \in \mathbb{Z} \right\}$$

of all integral combinations of  $n$  linear independent vectors  $\mathbf{b}_1, \dots, \mathbf{b}_n$  in  $\mathbb{R}^m$  ( $m \leq n$ ). We call matrix  $\mathbf{B} = [\mathbf{b}_1, \dots, \mathbf{b}_n] \in \mathbb{R}^{m \times n}$  a basis of lattice  $\Lambda$ . Using matrix notation, a lattice can be defined as  $\Lambda(\mathbf{B}) = \{\mathbf{B}\mathbf{x} \mid \mathbf{x} \in \mathbb{Z}^n\}$ .

The discrete Gaussian distribution of a lattice  $\Lambda$ , parameter  $s$  and center  $\mathbf{v}$  is defined as  $D_{\Lambda, \mathbf{v}, s}(\mathbf{x}) = \frac{\rho_{\mathbf{v}, s}(\mathbf{x})}{\rho_{\mathbf{v}, s}(\Lambda)}$ .

**Lemma 1 ([41]Lemma 3.3).** *For any lattice  $\Lambda \in \mathbb{R}^m$  and positive real number  $s > 0$ , we have  $\Pr_{\mathbf{x} \leftarrow D_s^m}[\|\mathbf{x}\| \leq 2\sqrt{m}s] \geq 1 - 2^{-m}$ .*

**Definition 1** *Let  $m \geq n \geq 1$  and  $q \geq 2$ . For arbitrary matrix  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  and vector  $\mathbf{u} \in \mathbb{Z}_q^n$  define  $m$ -dimensional full-rank integer lattices and its shift:*

$$\Lambda^\perp(\mathbf{A}) = \{\mathbf{z} \in \mathbb{Z}^m : \mathbf{A}\mathbf{z} = \mathbf{0} \pmod{q}\},$$

$$\Lambda_{\mathbf{u}}^\perp(\mathbf{A}) = \{\mathbf{z} \in \mathbb{Z}^m : \mathbf{A}\mathbf{z} = \mathbf{u} \pmod{q}\}.$$

Short Integer Solution (SIS) problem and Inhomogeneous Short Integer Solution (ISIS) problem are two average-case hard problems frequently used in lattice-based cryptography constructions.

**Definition 2 (SIS $_{q,n,m,\beta}$  problem)** *Given a uniformly chosen matrix  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$ , find  $\mathbf{x} \in \Lambda^\perp(\mathbf{A})$  and  $0 < \|\mathbf{x}\| \leq \beta$ .*

**Definition 3 (ISIS $_{q,n,m,\beta}$  problem)** *Given a uniformly chosen matrix  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  and vector  $\mathbf{u} \in \mathbb{Z}_q^n$ , find  $\mathbf{x} \in \Lambda_{\mathbf{u}}^\perp(\mathbf{A})$  and  $0 < \|\mathbf{x}\| \leq \beta$ .*

According to [28], if  $q \geq \omega(\sqrt{n \log n})\beta$  and  $m, \beta = \text{poly}(n)$ , then SIS $_{q,n,m,\beta}$  and ISIS $_{q,n,m,\beta}$  is at least as hard as a standard worst-case lattice problem SIVP $_\gamma$  (Shortest Independent Vector Problem) with  $\gamma = \tilde{O}(\beta n)$ . Similarly, R-SIS (R-ISIS) problems are defined as an analogue of SIS (ISIS) problem in ideal lattices.

**Definition 4 (R-SIS $_{q,m,\beta}$  problem)** *Given a uniformly chosen vector  $\hat{\mathbf{a}} \in \mathcal{R}_q^m$ , find  $\hat{\mathbf{x}} \in \mathcal{R}^m$  such that  $\hat{\mathbf{a}}^T \cdot \hat{\mathbf{x}} = 0$  and  $0 < \|\hat{\mathbf{x}}\| \leq \beta$ .*

**Definition 5 (R-ISIS $_{q,m,\beta}$  problem)** *Given a uniformly chosen vector  $\hat{\mathbf{a}} \in \mathcal{R}_q^m$  and a ring element  $\mathbf{u} \in \mathcal{R}_q$ , find  $\hat{\mathbf{x}} \in \mathcal{R}^m$  such that  $\hat{\mathbf{a}}^T \cdot \hat{\mathbf{x}} = \mathbf{u}$  and  $0 < \|\hat{\mathbf{x}}\| \leq \beta$ .*

The R-SIS problem was concurrently introduced in [48, 42]. According to [42], the R-SIS $_{q,m,\beta}$  is as hard as the SVP $_\gamma$  (Shortest Vector Problem) for  $\gamma = \tilde{O}(n\beta)$  in all lattice that are ideals in  $\mathcal{R}$  if  $\mathcal{R} = \mathbb{Z}[x]/(x^n + 1)$ , where  $n$  is a power of 2.

**Definition 6 (NTRU assumption)** Let  $\mathbf{a} = \mathbf{g}/\mathbf{f}$  over  $\mathcal{R}_q$  where  $\|\mathbf{f}, \mathbf{g}\|_1$  is bounded by some parameter  $\beta < q$ . The NTRU assumption says it is hard to distinguish  $\mathbf{a}$  from a uniformly random element from  $\mathcal{R}_q$ .

Over the years, there has been a few different versions of the NTRU assumption [34, 51, 40]. Here we use a decisional version that is most convenient for our proof. Note that this assumption holds as long as GapSVP problem is hard for NTRU lattices.

### 2.3 Preimage Sampleable Functions and Falcon

Generating a ‘hard’ public basis  $\mathbf{A}$  (chosen at random from some appropriate distribution) of some lattice  $\Lambda$ , together with a ‘good’ trapdoor basis  $\mathbf{T}$  has been studied since the work of Ajtai [2]. In 2008, Gentry, Peikert and Vaikuntanathan [29] construct a preimage sampleable function using the ‘hard’ public basis and trapdoor basis, and apply it as a building block to lattice-based signature schemes. This celebrated work (referred to as the GPV framework) is followed by a sequence of improvements. Alwen and Peikert [5] is able to generate a shorter trapdoor, compared to [29]; while Peikert [47] provides a parallelizable algorithm to sample preimages. To the best of our knowledge, the most efficient construction following this direction while maintaining a security proof is due to Micciancio and Peikert [44]. Here we re-state one of their results.

**Theorem 1 ([44], Theorem 5.1).** *There exists an efficient algorithm `GenBasis` ( $1^n, 1^m, q$ ) that given any integers  $n \leq 1, q \leq 2$ , and sufficiently large  $m = O(n \log q)$ , outputs a parity-check matrix  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  and a ‘trapdoor’  $\mathbf{T}$  such that the distribution of  $\mathbf{A}$  is  $\text{negl}(n)$ -far from uniform. Moreover, there is an efficient algorithm `PreSample`. With overwhelming probability over all random choices, for any  $\mathbf{u} \in \mathbb{Z}_q^n$  and large enough  $s = O(\sqrt{n \log q})$ , `PreSample`( $\mathbf{A}, \mathbf{T}, \mathbf{u}, s$ ) samples from a distribution within  $\text{negl}(n)$  statistical distance of  $D_{\Lambda_{\mathbf{u}}^+(\mathbf{A}), s \cdot \omega(\sqrt{\log n})}$ .*

On the other hand, the most efficient GPV construction in practice is due to Prest et al. [23, 27] using NTRU lattices [34]. The corresponding signature scheme is named FALCON [27].

FALCON is a candidate lattice-based signature scheme to the NIST post-quantum standardization process [45]. It is the resurrection of NTRUSign [32] with the aforementioned GPV framework for transcript security [29, 23], and a fast Fourier sampling for efficiency [24]. It is by far the most practical candidates among all submitted proposals, in terms of the combined sizes of public keys and signatures; and the only solution that provides a preimage sampleable function. In terms of security,

- FALCON stems from the provable secure GPV construction [28], under the (quantum) random oracle model [13];
- although the parameters in FALCON does not support GPV’s security proof, they are robust against best known attacks<sup>4</sup>.

<sup>4</sup> In practical lattice-based cryptography, it is common to derive parameters from best known attacks other than security proofs. For example, see [4, 3].

The high level description of FALCON is in Appendix 6.3.

### 3 Our Generic Constructions

In this section, we present our generic construction of  $\text{CH}^+$  and our (linkable) ring signature scheme based on  $\text{CH}^+$ . The syntax and security notions of (linkable) ring signature can be found in Appendix 6.1 and 6.2.

#### 3.1 Chameleon Hash Plus

$\text{CH}^+$  can be considered as a variant of Chameleon hash functions. A  $\text{CH}^+$  consists of four algorithms, namely, **SetUp**, **TrapGen**, **Hash** and **Inv**, as follow:

- **SetUp**( $1^\lambda$ )  $\rightarrow$   $\text{param}^{\text{ch}}$ : On input security parameter  $1^\lambda$ , this algorithm generates system parameter  $\text{param}^{\text{ch}}$ .  $\text{param}^{\text{ch}}$  will be an implicit input to **Hash** and **Inv**.
- **TrapGen**( $1^\lambda$ )  $\rightarrow$   $(\text{hk}, \text{tr})$ : This algorithm takes security parameter  $1^\lambda$  as input and returns a pair  $(\text{hk}, \text{tr})$  where  $\text{hk}$  and  $\text{tr}$  are respectively is a hash key and a trapdoor.
- **Hash**( $\text{hk}, m, r$ )  $\rightarrow$   $C$ : On input hash key  $\text{hk}$ , message  $m$  and randomness  $r$ , this algorithm returns hash output  $C$ .
- **Inv**( $\text{hk}, \text{tr}, C, m'$ )  $\rightarrow$   $r'$ : On input hash key  $\text{hk}$ , trapdoor  $\text{tr}$ , hash output  $C$  and message  $m'$ , this algorithm returns randomness  $r'$  s.t.  $\text{Hash}(\text{hk}, m', r') = C$ .

We require  $\text{CH}^+$  to satisfy following requirements:

1.  $\text{CH}^+$  should be one-way and collision resistant. In other words, for all PPT  $\mathcal{A}$ , there exists a negligible function  $\text{negl}(\lambda)$  such that

$$\begin{aligned} & \Pr\{(m_0, r_0), (m_1, r_1)\} \leftarrow \mathcal{A}(1^\lambda, \text{hk}, \text{param}^{\text{ch}}) : (m_0, r_0) \neq \\ & (m_1, r_1) \wedge \text{Hash}(\text{hk}, m_0, r_0) = \text{Hash}(\text{hk}, m_1, r_1)\} = \text{negl}(\lambda); \\ & \Pr[(m, r) \leftarrow \mathcal{A}(1^\lambda, C, \text{hk}, \text{param}^{\text{ch}}) : \text{Hash}(\text{hk}, m, r) = C] = \text{negl}(\lambda). \end{aligned}$$

2. For hash key  $\text{hk}$  generated from **TrapGen**, assuming the range of  $\text{hk}$  is  $R_{\text{hk}}$ , the distribution of  $\text{hk}$  should be either statistically close to uniform in  $R_{\text{hk}}$ ; or computationally close to the uniform distribution with an additional property that the probability a randomly sampled  $\bar{\text{hk}} \leftarrow_{\S} R_{\text{hk}}$  has a trapdoor is negligible.
3. For  $r'$  generated from **Inv**, the distribution of  $r'$  should be with  $\text{negl}(\lambda)$  distance from the distribution where  $r$  is sampled from.

Looking ahead, in the next section, we will show how to build  $\text{CH}^+$  from standard lattice problems and from NTRU assumptions.

### 3.2 A New Framework for Ring Signatures

Our ring signature is constructed as follows:

- **Setup**( $1^\lambda$ )  $\rightarrow$  **param**: On input the security parameter  $1^\lambda$ , this algorithm chooses a hash function  $\mathcal{H} : \{*\} \rightarrow D_b$ . It also runs **Setup**( $1^\lambda$ )  $\rightarrow$  **param**<sup>ch</sup>.
- **KeyGen**  $\rightarrow$  (sk, pk): This algorithm generates  $(\text{hk}, \text{tr}) \leftarrow \text{TrapGen}(1^\lambda)$ . Then it sets public key  $\text{pk} = \text{hk}$  and secret key  $\text{sk} = \text{tr}$ .
- **Signing**( $\text{sk}_\pi, \mu, L_{\text{pk}}$ )  $\rightarrow$   $\sigma$ : On input a message  $\mu$ , a list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_\ell\}$ , and a signing key  $\text{sk}_\pi = \text{tr}_\pi$  of  $\text{pk}_\pi = \text{hk}_\pi \in L_{\text{pk}}$ , the signing algorithm runs as follow:
  1. For  $i \in [1, \dots, \ell]$  and  $i \neq \pi$ , pick  $m_i$  and  $r_i$  at random. Compute  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ . For  $i = \pi$ , pick  $C_\pi$  at random.
  2. Compute  $m_\pi$  such that

$$m_1 \oplus \dots \oplus m_\pi \oplus \dots \oplus m_\ell = \mathcal{H}(\mu, C_1, \dots, C_\ell, L_{\text{pk}}).$$

3. Given  $m_\pi$  and  $C_\pi$ , invoke  $\text{Inv}(\text{hk}_\pi, \text{tr}_\pi, C_\pi, m_\pi) \rightarrow r_\pi$ .  
The ring signature of  $\mu$  and  $L_{\text{pk}}$  is  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell)\}$ .
- **Verification**( $\mu, \sigma, L_{\text{pk}}$ )  $\rightarrow$  *accept/reject*: On input a message  $\mu$ , a signature  $\sigma$  and a list of user public keys  $L_{\text{pk}}$ , the verification algorithm first phrases  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell)\}$ . It then checks whether each pair of  $(m_i, r_i)$  satisfies  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$  for all  $i \in [1, \dots, \ell]$  and whether  $m_1 \oplus \dots \oplus m_\ell = \mathcal{H}(\mu, C_1, \dots, C_\ell, L_{\text{pk}})$ . If yes, output *accept*. Otherwise, output *reject*.

### 3.3 A New Framework for Linkable Ring Signatures

Our linkable ring signature is constructed as follows:

- **Setup**( $1^\lambda$ )  $\rightarrow$  **param**: On input the security parameter  $1^\lambda$ , this algorithm chooses two hash functions  $\mathcal{H}$  and  $\mathcal{H}_1$ . It also runs **Setup**( $1^\lambda$ )  $\rightarrow$  **param**<sup>ch</sup> and selects a one-time signature scheme  $\Pi^{OTS} = \{\text{OKeygen}, \text{OSign}, \text{Over}\}$ .
- **KeyGen**  $\rightarrow$  (sk, pk):
  1. This algorithm first generates  $(\text{hk}, \text{tr}) \leftarrow \text{TrapGen}(1^\lambda)$ .
  2. It also generates a pair of  $\Pi^{OTS}$  public key and secret key  $(\text{opk}, \text{osk}) \leftarrow \text{OKeygen}(1^\lambda)$  and computes  $\text{mk} = \mathcal{H}_1(\text{opk})$ .
  3. It computes  $\text{hk}' = \text{hk} \oplus \text{mk}$ .
  4. It sets public key  $\text{pk} = \text{hk}'$  and secret key  $\text{sk} = \{\text{tr}, \text{opk}, \text{osk}\}$ .
- **Signing**( $\text{sk}_\pi, \mu, L_{\text{pk}}$ )  $\rightarrow$   $\sigma$ : On input a message  $\mu$ , a list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_\ell\}$ , and a signing key  $\text{sk}_\pi = \{\text{tr}_\pi, \text{opk}_\pi, \text{osk}_\pi\}$  of  $\text{pk}_\pi = \text{hk}'_\pi \in L_{\text{pk}}$ , the signing algorithm runs as follow:
  1. Compute  $\text{mk}_\pi = \mathcal{H}_1(\text{opk}_\pi)$ .
  2. For  $i \in [1, \dots, \ell]$  and  $i \neq \pi$ , pick  $m_i$  and  $r_i$  at random. Compute  $\text{hk}_i = \text{hk}'_i \oplus \text{mk}_\pi$  and  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ . For  $i = \pi$ , pick  $C_\pi$  at random.
  3. Compute  $m_\pi$  such that

$$m_1 \oplus \dots \oplus m_\pi \oplus \dots \oplus m_\ell = \mathcal{H}(\mu, C_1, \dots, C_\ell, L_{\text{pk}}).$$

4. Given  $m_\pi$  and  $C_\pi$ , compute  $r_\pi \leftarrow \text{Inv}(\text{hk}_\pi, \text{tr}_\pi, C_\pi, m_\pi)$ .
  5. Compute one-time signature  $\text{sig} = \text{OSign}(\text{osk}_\pi; (m_1, r_1), \dots, (m_\ell, r_\ell), L_{\text{pk}}, \text{opk}_\pi)$ .
- The linkable ring signature of  $\mu$  and  $L_{\text{pk}}$  is  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}_\pi, \text{sig}\}$ .
- **Verification** $(\mu, \sigma, L_{\text{pk}}) \rightarrow \text{accept/reject}$ : On input a message  $\mu$ , a signature  $\sigma$  and a list of user public keys  $L_{\text{pk}} = \{\text{hk}'_1, \dots, \text{hk}'_\ell\}$ , the verification algorithm first phrases  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}, \text{sig}\}$ . This algorithm runs as follow:
    1. It first computes  $\text{mk} = \mathcal{H}_1(\text{opk})$ . It also computes  $\text{hk}_i = \text{hk}'_i \oplus \text{mk}$  and  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$  for all  $i \in [1, \dots, \ell]$ ;
    2. It checks whether  $m_1 \oplus \dots \oplus m_\ell = \mathcal{H}(\mu, C_1, \dots, C_\ell, L_{\text{pk}})$ ;
    3. Verify the signature via  $\text{OVer}(\text{opk}; \text{sig}; (m_1, r_1), \dots, (m_\ell, r_\ell), L_{\text{pk}}, \text{opk})$ .
 If all pass, output *accept*. Otherwise, output *reject*.
  - **Link** $(\sigma_1, \sigma_2, \mu_1, \mu_2, L_{\text{pk}}^{(1)}, L_{\text{pk}}^{(2)}) \rightarrow \text{linked/unlinked}$ : On input two message signature pairs  $(\mu_1, \sigma_1)$  and  $(\mu_2, \sigma_2)$ , this algorithm first checks the validity of signatures  $\sigma_1$  and  $\sigma_2$ . If  $\text{Verification}(\mu_1, \sigma_1, L_{\text{pk}}^{(1)}) \rightarrow \text{accept}$  and  $\text{Verification}(\mu_2, \sigma_2, L_{\text{pk}}^{(2)}) \rightarrow \text{accept}$ , it phrases  $\sigma_1 = \{(m_1^{(1)}, r_1^{(1)}), \dots, (m_\ell^{(1)}, r_\ell^{(1)}), \text{opk}_1, \text{sig}_1\}$  and  $\sigma_2 = \{(m_1^{(2)}, r_1^{(2)}), \dots, (m_\ell^{(2)}, r_\ell^{(2)}), \text{opk}_2, \text{sig}_2\}$ . The algorithm outputs *linked* if  $\text{opk}_1 = \text{opk}_2$ . Otherwise, output *unlinked*.

Our generic ring signature scheme and linkable signature scheme both satisfy the security model we defined in Section 6.1 and Section 6.2 and are thus secure under random oracle model. Due to page limitation, we omit the security proof for our ring signature scheme. The detailed security proof for linkable ring signature scheme can be found in Appendix 6.7.

## 4 Instantiation

### 4.1 Instantiation of $\text{CH}^+$ from Standard Lattice

In this section, we are going to present our first instantiation of  $\text{CH}^+$  from standard lattice.

**Setup** $(1^\lambda) \rightarrow \mathbf{H}$ : On input the security parameter  $1^\lambda$ , this algorithm randomly samples a matrix  $\mathbf{H} \leftarrow_{\mathcal{S}} \mathbb{Z}_q^{n \times k}$ . The matrix  $\mathbf{H}$  will be an implicit input to **Hash** and **Inv** algorithm.

**TrapGen** $(1^\lambda) \rightarrow (\mathbf{A}, \mathbf{T})$ : This algorithm runs **GenBasis** $(1^n, 1^m, q) \rightarrow (\mathbf{A}, \mathbf{T})$  where  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  is a parity-check matrix and  $\mathbf{T}$  is a ‘good’ trapdoor basis of  $\Lambda^\perp(\mathbf{A})$ .

**Hash** $(\mathbf{A}, \mathbf{b}, \mathbf{r}) \rightarrow \mathbf{c}$ : On input hash key  $\mathbf{A}$ , binary message vector  $\mathbf{b} \in \{0, 1\}^k$  and randomness vector  $\mathbf{r} \leftarrow D_s^m$ , this algorithm computes  $\mathbf{c} = \mathbf{Hb} + \mathbf{Ar}$  and returns  $\mathbf{c}$ .

**Inv** $(\mathbf{A}, \mathbf{T}, \mathbf{c}, \mathbf{b}')$   $\rightarrow \mathbf{r}'$ : On hash key  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  and its trapdoor  $\mathbf{T}$ , a vector  $\mathbf{c} \in \mathbb{Z}_q^n$ , a binary vector  $\mathbf{b}' \in \{0, 1\}^k$ , it computes  $\mathbf{u} = \mathbf{c} - \mathbf{Hb}'$  and  $\mathbf{r}' = \text{PreSample}(\mathbf{A}, \mathbf{T}, \mathbf{u}, s)$ .

Now we argue that this instantiation satisfies our requirements of  $\text{CH}^+$  in Section 3.1.

- Our instantiation is collision resistant and one-way if  $\text{SIS}_{q,n,m',\beta}$  and  $\text{ISIS}_{q,n,m',\beta}$  are hard for  $m' = m + k$ ,  $\beta = \sqrt{8ms^2 + 2k}$  and  $\beta = \sqrt{4ms^2 + k}$  respectively.
- For the second requirement, according to Theorem 1, we have the distribution of parity-check matrix  $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$  generated from **GenBasis** algorithm is within  $\text{negl}(n)$  far from uniform. Thus, the distribution of  $\mathbf{A}$  is statistically close to uniform in  $\mathbb{Z}_q^{n \times m}$ . Our instantiation satisfies the second requirement.
- For the third requirement, this instantiation requires that randomness vector  $\mathbf{r}$  is sampled from Gaussian distribution  $D_s^m$ . According to Theorem 1, if we set deviation  $s$  appropriately (i.e., greater than the smooth parameter of  $\mathbf{T}$ , see [29]), the random vector  $\mathbf{r}'$  sampled by algorithm **Inv** is within  $\text{negl}(n)$  statistical distance of  $D_s^m$ . Thus our instantiation satisfies the third requirement.

## 4.2 Instantiation of $\text{CH}^+$ from NTRU

The FALCON-based  $\text{CH}^+$  scheme consists of following algorithms:

**Setup**( $1^\lambda$ )  $\rightarrow$  ( $\mathbf{h}, D_{\mathbf{b}}, D_{\mathbf{r}}$ ): On input the security parameter  $1^\lambda$ , this algorithm firstly sets up the polynomial ring  $\mathcal{R}_q$  and samples  $\mathbf{h} \leftarrow_{\S} \mathcal{R}_q$ . It also sets related distributions:

- $D_{\mathbf{b}}$ : a uniform distribution over  $\mathcal{R}_q$  with binary coefficients;
- $D_{\mathbf{r}}$ : a discrete Gaussian distribution over  $\mathcal{R}_q \times \mathcal{R}_q$ .

**TrapGen**( $1^\lambda$ )  $\rightarrow$  ( $\mathbf{a}, \mathbf{T}$ ): This algorithm takes security parameter  $1^\lambda$  as input and then runs FALCON key generation function to obtain a tuple  $(\mathbf{a}, \mathbf{T})$  where the public description of  $\text{CH}^+$ , namely,  $\mathbf{a} = \mathbf{g}/\mathbf{f}$  is computationally indistinguishable from uniform over  $\mathcal{R}_q$  under NTRU assumption;  $\mathbf{T} := \begin{bmatrix} \mathbf{f} & \mathbf{g} \\ \mathbf{f} & \mathbf{g} \end{bmatrix}$  is the trapdoor of  $\mathbf{a}$ .

**Hash**( $\mathbf{a}, \mathbf{b}, \mathbf{r}$ )  $\rightarrow$   $\mathbf{c}$ : On input a hash key  $\mathbf{a}$ , a binary message string  $\mathbf{b} \in D_{\mathbf{b}}$  and randomness  $\mathbf{r} := (\mathbf{r}_0, \mathbf{r}_1) \in D_{\mathbf{r}}$ , this algorithm returns a hash output  $\mathbf{c} := \mathbf{r}_0 + \mathbf{a}\mathbf{r}_1 + \mathbf{h}\mathbf{b} \in \mathcal{R}_q$ .

**Inv**( $\mathbf{a}, \mathbf{T}, \mathbf{c}, \mathbf{b}'$ )  $\rightarrow$   $\mathbf{r}'$ : On input hash key  $\mathbf{a}$ , its trapdoor  $\mathbf{T}$ , a value  $\mathbf{c} \in D_{\mathbf{c}}$  and a binary message  $\mathbf{b}'$ , this algorithm

- Compute  $\mathbf{u} = \mathbf{c} - \mathbf{b}'\mathbf{h}$ ;
- Generate a falcon signature  $\mathbf{r}' := (\mathbf{r}'_0, \mathbf{r}'_1)$  on  $\mathbf{u}$  such that  $\mathbf{r}'_0 + \mathbf{r}'_1\mathbf{a} = \mathbf{u}$ .

It returns  $\mathbf{r}' \in D_{\mathbf{r}}$  such that  $\text{Hash}(\mathbf{a}, \mathbf{b}', \mathbf{r}') = \mathbf{c}$ . The distribution of  $\mathbf{r}'$  will be identical to the distribution of  $\mathbf{r}$  used in **Hash** due to the property of GPV sampler.

This instantiation satisfies our requirements of  $\text{CH}^+$  in Section 3.1.

- The one-wayness and collision resistance of this instantiation is based on NTRU assumption, R-SIS and R-ISIS. According to NTRU assumption,

$\mathbf{a}$  is computationally close to uniform. For a R-SIS $_{3,q,\beta}$  problem instance<sup>5</sup>  $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ , we can compute  $\{1, \mathbf{a}', \mathbf{h}'\} = \{\frac{\mathbf{e}_1}{\mathbf{e}_1}, \frac{\mathbf{e}_2}{\mathbf{e}_1}, \frac{\mathbf{e}_3}{\mathbf{e}_1}\}$ .  $\mathbf{a}'$  should be indistinguishable with a real hash key  $\mathbf{a}$ . By obtaining a collision  $\{\mathbf{r}_0^{(0)}, \mathbf{r}_1^{(0)}, \mathbf{b}^{(0)}\}, \{\mathbf{r}_0^{(1)}, \mathbf{r}_1^{(1)}, \mathbf{b}^{(1)}\}$  on hash key  $\mathbf{a}'$  and public parameter  $\mathbf{h}'$ . We have

$$((\mathbf{r}_0^{(0)} - \mathbf{r}_0^{(1)}) + \mathbf{a}'(\mathbf{r}_1^{(0)} - \mathbf{r}_1^{(1)}) + \mathbf{h}'(\mathbf{b}^{(0)} - \mathbf{b}^{(1)})) = 0.$$

We find a solution to the problem instance  $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ . We can use the similar way to argue the one-wayness of NTRU instantiation.

- Under NTRU assumption, FALCON public key is computationally indistinguishable from uniform; and the probability that a uniform sampled ring element  $\bar{\mathbf{a}} \leftarrow_{\S} \mathcal{R}_q$  having a FALCON trapdoor is negligible.
- FALCON is essentially a GPV sampler over NTRU. Therefore, according to Theorem 1, if the deviation of  $D_{\mathbf{r}}$  is greater than the smoothing parameter, then  $\mathbf{r}'$  generated by algorithm `lnv` will be within  $\text{negl}(n)$  statistical distance of  $D_{A_{\mathbb{U}}(\mathbf{a}),s}$ . Thus our instantiation satisfies the third requirement.

The full description of RAPTOR and linkable RAPTORis presented in Appendix 6.4 and 6.5.

## 5 Parameters and Implementation

Here we give some parameter figures for RAPTOR-512, instantiated with FALCON-512. Our RAPTOR-512 uses a signature size of  $(617 \times 2 + 32)\ell \approx 1.26\ell$  kilo bytes, where  $\ell$  is the number of users in a signature. This is because, for each tuple  $\{\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i\}$  within a ring signature, we need a pair of  $\mathbf{r}_{i,0}$  and  $\mathbf{r}_{i,1}$ , each of 617 bytes, and an additional 32 bytes for  $\mathbf{b}_i$  to avoid any search attacks [31]. This parameter set yields 114 bits security against classical attackers, and 103 bits security against quantum attackers, under the BKZ2.0 framework [19] with (quantum) sieving algorithm [4, 36].

As for linkable RAPTOR-512, we need an additional FALCON public key and signature which is of size  $897 + 617 \approx 1.5$  kilo bytes. This accounts for a total of  $(1.3\ell + 1.5)$  kilo bytes.

For conservative purpose, one may also choose FALCON-1024 for better security, which results in a signature size of  $2.5\ell$  kilo bytes for RAPTOR-1024, and  $(2.5\ell + 3)$  kilo bytes for linkable RAPTOR-1024. The security level for both schemes will be over 256 bits.

We implemented RAPTOR-512 on a typical laptop with an Intel 6600U processor. The performance is shown in Tables 1(a) and 1(b). Our source code is available at [6]. This is a proof-of-concept implementation. We did not take into account potential optimizations such as NTT-based ring multiplication and AVX-2 instructions. We leave those to future work.

<sup>5</sup> We require at least one of the three elements is invertible over  $\mathcal{R}_q$ . For FALCON-512, the probability is  $(1 - 1/q)^N \approx 96\%$ .

## 6 Appendix

### 6.1 Ring Signatures

In this section, we are going to give the syntax and security models for ring signatures.

**Syntax** A ring signature scheme usually is a tuple of four algorithms (**Setup**, **KeyGen**, **Signing**, **Verification**):

- **Setup**( $1^\lambda$ )  $\rightarrow$  **param**: On input security parameter  $1^\lambda$ , this algorithm generates system parameter **param**. We assume **param** is an implicit input to all the algorithms listed below.
- **KeyGen**  $\rightarrow$  (**sk**, **pk**): By taking system parameter **param**, this key generation algorithm generates a private signing key **sk** and a public verification key **pk**.
- **Signing**(**sk**,  $\mu$ ,  $L_{\text{pk}}$ )  $\rightarrow$   $\sigma$ : On input message  $\mu$ , a list of user public keys  $L_{\text{pk}}$ , and signing key **sk** of one of the public keys in  $L_{\text{pk}}$ , the signing algorithm outputs a ring signature  $\sigma$  on  $\mu$ .
- **Verification**( $\mu$ ,  $\sigma$ ,  $L_{\text{pk}}$ )  $\rightarrow$  *accept/reject*: On input message  $\mu$ , signature  $\sigma$  and list of user public keys  $L_{\text{pk}}$ , the verification algorithm outputs *accept* if  $\sigma$  is legitimately created; *reject*, otherwise.

*Correctness*: the scheme is correct if signatures generated according to above specification are always accepted during verification.

**Security Notions** The security requirements for a ring signature scheme have two aspects: unforgeability and anonymity. Before presenting their definitions, we first introduce the following oracles which can be used by adversaries in breaking the security of ring signature schemes:

- *Registration Oracle*  $\mathcal{RO}(\perp) \rightarrow \text{pk}_i$ : On request,  $\mathcal{RO}$  generates a new user and returns the public key of the new user.
- *Corruption Oracle*  $\mathcal{CO}(\text{pk}_i) \rightarrow \text{sk}_i$ : On input a user public key  $\text{pk}_i$  that is a query output of  $\mathcal{RO}$ ,  $\mathcal{CO}$  returns corresponding secret key  $\text{sk}_i$ .
- *Signing Oracle*  $\mathcal{SO}(\mu, L_{\text{pk}}, \text{pk}_\pi) \rightarrow \sigma$ : On input a list of user public keys  $L_{\text{pk}}$ , message  $\mu$  and the public key of the signer  $\text{pk}_\pi \in L_{\text{pk}}$ ,  $\mathcal{SO}$  returns a valid signature  $\sigma$  on  $\mu$  and  $L_{\text{pk}}$ .

*Unforgeability* The unforgeability of a ring signature scheme is defined via the following game, denoted by  $\text{Game}_{\text{forge}}$ , between an adversary  $\mathcal{A}$  and a challenger  $\mathcal{C}$ .

- *Setup*. The challenger  $\mathcal{C}$  runs **Setup** with security parameter  $1^\lambda$  and generates system parameter **param**.  $\mathcal{C}$  sends **param** to  $\mathcal{A}$ .
- *Query*. The adversary  $\mathcal{A}$  may query  $\mathcal{RO}$ ,  $\mathcal{CO}$  and  $\mathcal{SO}$  for a polynomial bounded number of times in an adaptive manner.

- *Output.* The adversary  $\mathcal{A}$  outputs a forgery  $(\mu^*, \sigma^*, L_{\text{pk}}^*)$ .  $\mathcal{A}$  wins  $\text{Game}_{\text{forge}}$  if
  - **Verification** $(\mu^*, \sigma^*, L_{\text{pk}}^*) = \text{accept}$ ;
  - $(\mu^*, L_{\text{pk}}^*)$  has not been queried by  $\mathcal{A}$ ;
  - all public keys in  $L_{\text{pk}}^*$  should be outputs of  $\mathcal{RO}$ ; and
  - no public key in  $L_{\text{pk}}^*$  has been input to  $\mathcal{CO}$ .

The advantage of  $\mathcal{A}$ , denoted by  $\text{adv}_{\mathcal{A}}^{\text{forge}}$ , is defined by the probability that  $\mathcal{A}$  wins  $\text{Game}_{\text{forge}}$ :

$$\text{adv}_{\mathcal{A}}^{\text{forge}} = \Pr[\mathcal{A} \text{ wins } \text{Game}_{\text{forge}}]$$

**Definition 7 (Unforgeability)** *A ring signature scheme (**KeyGen**, **Signing**, **Verification**) is said to be unforgeable if for any polynomial-time adversary  $\mathcal{A}$ ,  $\text{adv}_{\mathcal{A}}^{\text{forge}}$  is negligible.*

*Anonymity* For a ring signature scheme, this notion captures that it is impossible for an adversary to identify the actual signer with probability greater than  $\frac{1}{n}$  where  $n$  is the size of the ring. More specifically, the anonymity of a ring signature scheme can be defined by the following game, denoted by  $\text{Game}_{\text{anon}}$ , between adversary  $\mathcal{A}$  and challenger  $\mathcal{C}$ :

- *Setup.* The challenger  $\mathcal{C}$  runs **Setup** with security parameter  $1^\lambda$  and sends the system parameter **param** to  $\mathcal{A}$ .
- *Query.* The adversary  $\mathcal{A}$  may query  $\mathcal{RO}$  and  $\mathcal{CO}$  in an adaptive manner.
- *Challenge.*  $\mathcal{A}$  picks a list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \text{pk}_2, \dots, \text{pk}_n\}$  and a message  $\mu$ .  $\mathcal{A}$  sends  $(L_{\text{pk}}, \mu)$  to  $\mathcal{C}$ .  $\mathcal{C}$  randomly picks  $\pi \in \{1, \dots, n\}$  and runs **Signing** $(\text{sk}_\pi, \mu, L_{\text{pk}}) \rightarrow \sigma$ .  $\mathcal{C}$  sends  $\sigma$  to  $\mathcal{A}$ .
- *Output.*  $\mathcal{A}$  outputs a guess  $\pi^* \in \{1, \dots, n\}$ .

$\mathcal{A}$  wins  $\text{Game}_{\text{anon}}$  if  $\pi^* = \pi$ . The advantage of  $\mathcal{A}$  is defined by

$$\text{adv}_{\mathcal{A}}^{\text{anon}} = \left| \Pr[\pi^* = \pi] - \frac{1}{n} \right|.$$

**Definition 8 (Anonymity)** *A ring signature scheme (**KeyGen**, **Signing**, **Verification**) is said to be anonymous (resp. unconditionally anonymous) if for any polynomial-time adversary (resp. unbounded adversary)  $\mathcal{A}$ ,  $\text{adv}_{\mathcal{A}}^{\text{anon}}$  is negligible.*

## 6.2 Linkable Ring Signatures

In this section, we are going to present the syntax and security requirements of linkable ring signatures. We emphasize that the linkable ring signature here is one-time linkable ring signature and the public key for a signer is only supposed to use once.

**Syntax** A linkable ring signature scheme usually consists of five algorithms, namely, (**Setup**, **KeyGen**, **Signing**, **Verification**, **Link**):

- **Setup**( $1^\lambda$ )  $\rightarrow$  **param**: On input the security parameter  $1^\lambda$ , this algorithm generates the system parameter **param**. We assume **param** is an implicit input to all the algorithms listed below.
- **KeyGen**  $\rightarrow$  (**sk**, **pk**): By taking the system parameter **param**, this key generation algorithm generates a private signing key **sk** and a public verification key **pk**.
- **Signing**(**sk**,  $\mu$ ,  $L_{\text{pk}}$ )  $\rightarrow$   $\sigma$ : On input a message  $\mu$ , a list of user public keys  $L_{\text{pk}}$ , and a signing key **sk** of one of the public keys in  $L_{\text{pk}}$ , the signing algorithm outputs a ring signature  $\sigma$  on  $\mu$ .
- **Verification**( $\mu$ ,  $\sigma$ ,  $L_{\text{pk}}$ )  $\rightarrow$  *accept/reject*: On input a message  $\mu$ , a signature  $\sigma$  and a list of user public keys  $L_{\text{pk}}$ , the verification algorithm outputs *accept* if  $\sigma$  is legitimately created, otherwise, output *reject*.
- **Link** ( $\sigma_1$ ,  $\sigma_2$ ,  $\mu_1$ ,  $\mu_2$ ,  $L_{\text{pk}}^{(1)}$ ,  $L_{\text{pk}}^{(2)}$ )  $\rightarrow$  *linked/unlinked*: Takes two messages  $\mu_1$ ,  $\mu_2$  and their signatures  $\sigma_1$  and  $\sigma_2$  as input, output *linked* or *unlinked*.

*Correctness*: the scheme is correct if

- signatures signed as above is always accepted during verification; and
- two legally signed signatures are linked if and only if they share a same signer.

**Security Notions** The security of a linkable ring signature should have four aspects, namely, unforgeability, anonymity, linkability and nonslanderability. Same as the security notions for ring signatures, there are also three oracles, namely,  $\mathcal{RO}$ ,  $\mathcal{CO}$  and  $\mathcal{SO}$  jointly model the ability of an adversary:

The security definition of unforgeability for linkable ring signatures remains the same as in section 6.1. The definitions of anonymity, linkability and nonslanderability are adopted from Liu et al. [38].

*Anonymity* We require that, for a secure linkable ring signature scheme, it should be impossible for an adversary to identify the actual signer with probability greater than  $\frac{1}{n}$  where  $n$  is the size of the ring. More specifically, the anonymity of a linkable ring signature scheme can be defined by the following game,  $\text{Game}_{\text{anon}}^*$ , held between adversary  $\mathcal{A}$  and challenger  $\mathcal{C}$ . The difference between  $\text{Game}_{\text{anon}}^*$  and  $\text{Game}_{\text{anon}}$  is that, in  $\text{Game}_{\text{anon}}^*$ ,  $\mathcal{A}$  is only allowed to query register oracle  $\mathcal{RO}$ .

- *Setup*. The challenger  $\mathcal{C}$  runs **Setup** with security parameter  $1^\lambda$  and sends the system parameter **param** to  $\mathcal{A}$ .
- *Query*. The adversary  $\mathcal{A}$  may query  $\mathcal{RO}$  in an adaptive manner.
- *Challenge*.  $\mathcal{A}$  picks a list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \text{pk}_2, \dots, \text{pk}_n\}$  and a message  $\mu$ . All public keys in  $L_{\text{pk}}$  should be query outputs of  $\mathcal{RO}$ .  $\mathcal{A}$  sends  $(L_{\text{pk}}, \mu)$  to  $\mathcal{C}$ .  $\mathcal{C}$  randomly picks  $\pi \in \{1, \dots, n\}$  and runs **Signing**(**sk** $_\pi$ ,  $\mu$ ,  $L_{\text{pk}}$ )  $\rightarrow$   $\sigma$ .  $\mathcal{C}$  sends  $\sigma$  to  $\mathcal{A}$ .

- *Output.*  $\mathcal{A}$  outputs a guess  $\pi^* \in \{1, \dots, n\}$ .

$\mathcal{A}$  wins  $\text{Game}_{\text{anon}}^*$  if  $\pi^* = \pi$ . The advantage of  $\mathcal{A}$  is defined by

$$\text{adv}_{\mathcal{A}}^{\text{anon}} = \left| \Pr[\pi^* = \pi] - \frac{1}{n} \right|.$$

**Definition 9 (Anonymity)** A linkable ring signature scheme is said to be anonymous (resp. unconditionally anonymous) if for any polynomial-time adversary (resp. unbounded adversary)  $\mathcal{A}$ ,  $\text{adv}_{\mathcal{A}}^{\text{anon}}$  is negligible.

*Linkability* This notion captures that **Link** algorithm always outputs *linked* for two signatures generated by a same signer. We use the following game,  $\text{Game}_{\text{link}}$ , between a challenger  $\mathcal{C}$  and an adversary  $\mathcal{A}$  to define linkability:

- *Setup.* The challenger  $\mathcal{C}$  runs **Setup** and gives  $\mathcal{A}$  system parameter **param**.
- *Query.* The adversary  $\mathcal{A}$  is given access to  $\mathcal{RO}$ ,  $\mathcal{CO}$ ,  $\mathcal{SO}$  and may query the oracles in an adaptive manner.
- *Output.*  $\mathcal{A}$  outputs  $k$  sets,  $\{L_{\text{pk}}^{(i)}, \mu_i, \sigma_i\}$  for  $i \in [1, \dots, k]$ , where  $L_{\text{pk}}^{(i)}$  is a list of public keys,  $\mu_i$  is message,  $\sigma_i$  is signature.

$\mathcal{A}$  wins the game if

- all  $\sigma_i$ s are not query output of  $\mathcal{SO}$ ;
- all public keys in  $L_{\text{pk}}^{(i)}$  are query output of  $\mathcal{RO}$ ;
- **Verification** $(\mu_i, \sigma_i, L_{\text{pk}}^{(i)}) = \text{Accept}$  ;
- $\mathcal{A}$  queried  $\mathcal{CO}$  less than  $k$  times; and
- **Link** $(\sigma_i, \sigma_j, \mu_i, \mu_j, L_{\text{pk}}^{(i)}, L_{\text{pk}}^{(j)}) = \text{unlinked}$  for  $i, j \in [1, \dots, k]$  and  $i \neq j$ .

The advantage of  $\mathcal{A}$  is defined by the probability  $\mathcal{A}$  wins  $\text{Game}_{\text{link}}$ :

$$\text{adv}_{\mathcal{A}}^{\text{link}} = \Pr[\mathcal{A} \text{ wins } \text{Game}_{\text{link}}]$$

**Definition 10 (Linkability)** A linkable ring signature scheme is linkable if for any polynomial-time adversary  $\mathcal{A}$ ,  $\text{adv}_{\mathcal{A}}^{\text{link}}$  is negligible.

*Nonslanderability* The nonslanderability requires that a signer cannot frame other honest signers for generating a signature linked with another signature not signed by the signer. We use the following game,  $\text{Game}_{\text{slander}}$ , to define the nonslanderability of a linkable ring signature scheme:

- *Setup.* The challenger  $\mathcal{C}$  runs **Setup** and gives  $\mathcal{A}$  system parameter **param**.
- *Query.* The adversary  $\mathcal{A}$  is given access to  $\mathcal{RO}$ ,  $\mathcal{CO}$ ,  $\mathcal{SO}$  and may query the oracles in an adaptive manner.
- *Challenge.*  $\mathcal{A}$  gives  $\mathcal{C}$  a list of public keys  $L_{\text{pk}}$ , a message  $\mu$  and a public key  $\text{pk}_{\pi} \in L_{\text{pk}}$ .  $\mathcal{C}$  runs **Signing** $(\text{sk}, \mu, L_{\text{pk}})$  and returns the corresponding signature  $\sigma$  to  $\mathcal{A}$ .  $\mathcal{A}$  still can queries oracles with arbitrary interleaving.
- *Output.*  $\mathcal{A}$  outputs a list of public keys  $L_{\text{pk}}^*$ , message  $\mu^*$ , and a signature  $\sigma^*$ .

$\mathcal{A}$  wins  $\text{Game}_{\text{slander}}$  if the following holds:

- **Verification** $(\mu^*, \sigma^*, L_{\text{pk}}^*) = \text{accept}$ ;
- $\text{pk}_\pi$  is not queried by  $\mathcal{A}$  to  $\mathcal{CO}$ ;
- $\text{pk}_\pi$  is not queried by  $\mathcal{A}$  as an insider to  $\mathcal{SO}$ ; and
- **Link** $(\sigma, \sigma^*, \mu, \mu^*) = \text{linked}$ .

The advantage of  $\mathcal{A}$  is defined by:

$$\text{adv}_{\mathcal{A}}^{\text{slander}} = \Pr[\mathcal{A} \text{ wins } \text{Game}_{\text{slander}}]$$

**Definition 11 (Nonslanderability)** *A linkable ring signature scheme is nonslanderable if for any polynomial-time adversary  $\mathcal{A}$ ,  $\text{adv}_{\mathcal{A}}^{\text{slander}}$  is negligible.*

**Theorem 2.** *[[10], Sec 3.2] If a linkable ring signature scheme is linkable and nonslanderable, it is also unforgeable.*

### 6.3 Falcon Signature Scheme

This section gives the high level description of FALCON signature scheme. The detail of the scheme can be found in [27]. Here we assume the signature scheme works over a polynomial ring  $\mathcal{R}_q := \mathbb{Z}_q[x]/(x^n + 1)$ .

- $\text{FALCON.KeyGen}(1^\lambda) \rightarrow (\mathbf{a}, \mathbf{T})$ : this algorithm takes security parameter  $1^\lambda$  as input and chooses random  $\mathbf{f}$  and  $\mathbf{g}$  polynomials ( $\mathbf{f}, \mathbf{g} \in \mathcal{R}_q$ ) using an appropriate distribution. The public key will be set as  $\mathbf{a} = \mathbf{g}/\mathbf{f}$  and the secret key  $\mathbf{T} := \begin{bmatrix} \mathbf{f} & \mathbf{g} \\ \bar{\mathbf{f}} & \bar{\mathbf{g}} \end{bmatrix}$  is the trapdoor of  $\mathbf{a}$ .  $\bar{\mathbf{f}}$  and  $\bar{\mathbf{g}}$  satisfy  $\mathbf{f}\bar{\mathbf{g}} - \mathbf{g}\bar{\mathbf{f}} = q \pmod{(x^n + 1)}$  and  $\mathbf{f}, \mathbf{g}, \bar{\mathbf{f}}, \bar{\mathbf{g}}$  should be short.
- $\text{FALCON.Sign}(\mathbf{a}, \mathbf{T}; \mu) \rightarrow (\mathbf{r}_0, \mathbf{r}_1)$ : the signing algorithm first hashing the message  $\mu$  into a polynomial  $\mathbf{c} \in \mathcal{R}_q$ . Then it uses the short trapdoor  $\mathbf{T}$  to produce a pair of short polynomials  $(\mathbf{r}_0, \mathbf{r}_1)$  such that  $\mathbf{r}_0 + \mathbf{a}\mathbf{r}_1 = \mathbf{c}$ .
- $\text{FALCON.Verify}(\mathbf{a}, (\mathbf{r}_0, \mathbf{r}_1), \mu) \rightarrow 0/1$ : this algorithm verifies that  $(\mathbf{r}_0, \mathbf{r}_1)$  is a pair of appropriately short polynomials and  $\mathbf{c} = \mathbf{r}_0 + \mathbf{a}\mathbf{r}_1$  where  $\mathbf{c}$  is the hash of message  $\mu$ . If all pass, output 1; otherwise, output 0.

### 6.4 Full Description of Raptor

Now we are ready to present our instantiation. FALCON works over a polynomial ring  $\mathcal{R}_q := \mathbb{Z}_q[x]/(x^n + 1)$  for  $n \in \{512, 1024\}$  and  $q = 12289$ . There is a third parameter set with a different, more complicated polynomial ring. For simplicity, we omit this parameter set.

**Setup** $(1^\lambda) \rightarrow \text{param}$ : On input the security parameter  $1^\lambda$ , this algorithm chooses a hash function  $\mathcal{H}: \{*\} \rightarrow \{0, 1\}^n$ , a suitable  $\mathcal{R}$  and distributions  $D_{\mathbf{b}}, D_{\mathbf{r}}$  for the security level, where  $D_{\mathbf{b}} := \{0, 1\}^{256}$ ,  $D_{\mathbf{r}} := \mathcal{D}_{\mathcal{R}, \eta}^2$ ,  $\mathcal{D}$  is a discrete Gaussian distribution over  $\mathcal{R}$  with deviation  $\eta$ , and  $\eta \approx 1.17\sqrt{q}$  is the smooth parameter. It also picks a public polynomial  $\mathbf{h} \leftarrow_{\mathcal{S}} \mathcal{R}_q$  at random as  $\text{param}^{\text{ch}}$ .

**KeyGen** $\rightarrow (\text{sk}, \text{pk})$ : This algorithm firstly generates  $(\mathbf{a}, \mathbf{f}, \mathbf{g}, \bar{\mathbf{f}}, \bar{\mathbf{g}}) \leftarrow \text{FALCON.KeyGen}(\text{param})$  where

1.  $\mathbf{a} = \mathbf{g}/\mathbf{f} \in \mathcal{R}_q$ ,
2.  $\mathbf{f} \times \bar{\mathbf{g}} - \mathbf{g} \times \bar{\mathbf{f}} = q$ ,
3.  $\|(\mathbf{f}, \mathbf{g})\|$  and  $\|(\bar{\mathbf{f}}, \bar{\mathbf{g}})\|$  are small.

Then it sets public key  $\mathbf{pk} = \{\mathbf{a}\}$  and secret key  $\mathbf{sk} = \{\mathbf{f}, \mathbf{g}, \bar{\mathbf{f}}, \bar{\mathbf{g}}\}$ .

**Signing**( $\mathbf{sk}_\pi, \mu, L_{\mathbf{pk}}, \text{param}$ )  $\rightarrow \sigma$ : On input message  $\mu$ , list of user public keys  $L_{\mathbf{pk}} = \{\mathbf{pk}_1, \dots, \mathbf{pk}_\ell\}$ , and signing key  $\mathbf{sk}_\pi = \{\mathbf{f}_\pi, \mathbf{g}_\pi, \bar{\mathbf{f}}_\pi, \bar{\mathbf{g}}_\pi\}$  of  $\mathbf{pk}_\pi = \{\mathbf{a}_\pi\}$ , and the system parameter  $\text{param}$ , the signing algorithm runs as follow:

1. For  $i \in [1, \dots, \ell]$  and  $i \neq \pi$ , picks  $\mathbf{b}_i \leftarrow_{\S} \{0, 1\}^{256}$  and  $(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}) \leftarrow \mathcal{D}_{\mathcal{R}, \eta}^2$ .  
Compute  $\mathbf{c}_i = \mathbf{r}_{i,0} + \mathbf{a}_i \mathbf{r}_{i,1} + \mathbf{h} \mathbf{b}_i$ .
2. For  $i = \pi$ , pick  $\mathbf{c}_\pi \leftarrow_{\S} \mathcal{R}_q$ .
3. Compute  $\mathbf{b}_\pi$  such that

$$\mathbf{b}_1 \oplus \dots \oplus \mathbf{b}_\pi \oplus \dots \oplus \mathbf{b}_\ell = \mathcal{H}(\mu, \mathbf{c}_1, \dots, \mathbf{c}_\ell).$$

4. Set  $\mathbf{u}_\pi = \mathbf{c}_\pi - \mathbf{h} \mathbf{b}_\pi$ .
5. Compute  $(\mathbf{r}_{\pi,0}, \mathbf{r}_{\pi,1}) = \text{FALCON.sign}(\mathbf{a}_\pi, \mathbf{sk}_\pi; \mathbf{u}_\pi)$  such that  $\mathbf{r}_{\pi,0} + \mathbf{r}_{\pi,1} \mathbf{a}_\pi = \mathbf{u}_\pi$ .

The ring signature of  $\mu$  and  $L_{\mathbf{pk}}$  is  $\sigma = \{(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i)\}_{i=1}^\ell$ .

**Verification**( $\mu, \sigma, L_{\mathbf{pk}}$ )  $\rightarrow \text{accept/reject}$ : On input message  $\mu$ , signature  $\sigma$  and a list of user public keys  $L_{\mathbf{pk}}$ , the verification algorithm performs as follows:

1. phrases  $\sigma = \{(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i)\}_{i=1}^\ell$ ;
2. checks whether for each tuple of  $(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i)$ ,  $\|\mathbf{r}_{i,0}\|, \|\mathbf{r}_{i,1}\| \leq B_1$  and  $\mathbf{b}_i \in D_{\mathbf{b}}$ ; outputs *reject* if not.
3. computes  $\mathbf{c}_i = \mathbf{r}_{i,0} + \mathbf{a}_i \mathbf{r}_{i,1} + \mathbf{h} \mathbf{b}_i$  for all  $i \in [1, \dots, \ell]$  and checks whether  $\mathbf{b}_1 \oplus \dots \oplus \mathbf{b}_\ell = \mathcal{H}(\mu, \mathbf{c}_1, \dots, \mathbf{c}_\ell)$ ; outputs *reject* if not.
4. outputs *accept*.

For a legitimately produced ring signature  $\sigma$ , each  $(\mathbf{r}_{i,0}, \mathbf{r}_{i,1})$  pair should be distributed according to  $\mathcal{D}_{\mathcal{R}, \eta}^2$ , thus the acceptance bound  $B_1$  of  $\mathbf{r}_{i,0}, \mathbf{r}_{i,1}$  should be  $\nu \eta \sqrt{n}$  where  $\nu$  is set such that  $\|\mathbf{r}_{i,0}\|, \|\mathbf{r}_{i,1}\| \leq B_1$  with probability  $1 - 2^{-\lambda}$  Lemma 1.

## 6.5 Full Description of Linkable Raptor

As shown in Section 3.3, one can convert RAPTOR into a one-time linkable one with a one-time signature scheme. For easiness of implementation, we will use also use FALCON to instantiate this signature scheme.

**Setup**( $1^\lambda$ )  $\rightarrow \text{param}$ : On input the security parameter  $1^\lambda$ , this algorithm chooses  $\mathcal{H}, D_{\mathbf{b}}, D_{\mathbf{r}}$  and  $\eta$  as in RAPTOR. It also chooses a hash function  $\mathcal{H}_1: \{*\} \rightarrow \mathcal{R}_q$ .

**KeyGen** $\rightarrow (\mathbf{sk}, \mathbf{pk})$ : This algorithm firstly generates

- $(\mathbf{a}, \mathbf{f}, \mathbf{g}, \bar{\mathbf{f}}, \bar{\mathbf{g}}) \leftarrow \text{FALCON.KeyGen}(\text{param})$ , and
- $(\mathbf{a}_{ots}, \mathbf{f}_{ots}, \mathbf{g}_{ots}, \bar{\mathbf{f}}_{ots}, \bar{\mathbf{g}}_{ots}) \leftarrow \text{FALCON.KeyGen}(\text{param})$

Then it sets  $\mathbf{a}' := \mathbf{a} + \mathcal{H}_1(\mathbf{a}_{ots}) \bmod q$ . The public key  $\text{pk} = \mathbf{a}'$  and secret key  $\text{sk} = \{\mathbf{f}, \mathbf{g}, \bar{\mathbf{f}}, \bar{\mathbf{g}}, \mathbf{f}_{ots}, \mathbf{g}_{ots}, \bar{\mathbf{f}}_{ots}, \bar{\mathbf{g}}_{ots}, \mathbf{a}_{ots}\}$ .

**Signing**( $\text{sk}_\pi, \mu, L_{\text{pk}}, \text{param}$ )  $\rightarrow \sigma$ : On input message  $\mu$ , list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_\ell\}$ , and signing key  $\text{sk}_\pi = \{\mathbf{f}_\pi, \mathbf{g}_\pi, \bar{\mathbf{f}}_\pi, \bar{\mathbf{g}}_\pi, \mathbf{f}_{ots}, \mathbf{g}_{ots}, \bar{\mathbf{f}}_{ots}, \bar{\mathbf{g}}_{ots}, \mathbf{a}_{ots}\}$  of  $\text{pk}_\pi = \mathbf{a}'_\pi$ , and the system parameter  $\text{param}$ , the signing algorithm runs as follow:

1. For  $i \in [1, \dots, \ell]$ , compute  $\mathbf{a}_i = \mathbf{a}'_i - \mathcal{H}_1(\mathbf{a}_{ots}) \bmod q$ .
2. For  $i \in [1, \dots, \ell]$  and  $i \neq \pi$ , picks  $\mathbf{b}_i \leftarrow_{\mathcal{R}} \{0, 1\}^{256}$  and  $(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}) \leftarrow \mathcal{D}_{\mathcal{R}, \eta}^2$ . Compute  $\mathbf{c}_i = \mathbf{r}_{i,0} + \mathbf{a}_i \mathbf{r}_{i,1} + \mathbf{h}_i \mathbf{b}_i$ .
3. For  $i = \pi$ , pick  $\mathbf{c}_\pi \leftarrow_{\mathcal{R}} \mathcal{R}_q$ .
4. Compute  $\mathbf{b}_\pi$  such that

$$\mathbf{b}_1 \oplus \dots \oplus \mathbf{b}_\pi \oplus \dots \oplus \mathbf{b}_\ell = \mathcal{H}(\mu, \mathbf{c}_1, \dots, \mathbf{c}_\ell).$$

5. Set  $\mathbf{u}_\pi = \mathbf{c}_\pi - \mathbf{h} \mathbf{b}_\pi$ .
6. Set  $(\mathbf{r}_{\pi,0}, \mathbf{r}_{\pi,1}) = \text{FALCON.sign}(\mathbf{a}_\pi, (\mathbf{f}_\pi, \mathbf{g}_\pi, \bar{\mathbf{f}}_\pi, \bar{\mathbf{g}}_\pi); \mathbf{u}_\pi)$  such that  $\mathbf{r}_{\pi,0} + \mathbf{r}_{\pi,1} \mathbf{a}_\pi = \mathbf{u}_\pi$ .
7. Compute  $\text{sig} := \text{FALCON.sign}(\mathbf{a}_{ots}, (\mathbf{f}_{ots}, \mathbf{g}_{ots}, \bar{\mathbf{f}}_{ots}, \bar{\mathbf{g}}_{ots}); (\{\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i\}_{i=1}^\ell, \{\mathbf{a}'_i\}_{i=1}^\ell, \mathbf{a}_{ots}))$ .

The ring signature of  $\mu$  and  $L_{\text{pk}}$  is  $\sigma = \{\{\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i\}_{i=1}^\ell, \mathbf{a}_{ots}, \text{sig}\}$ .

**Verification**( $\mu, \sigma, L_{\text{pk}}$ )  $\rightarrow \text{accept/reject}$ : On input message  $\mu$ , signature  $\sigma$  and a list of user public keys  $L_{\text{pk}}$ , the verification algorithm performs as follows:

1. phrases  $\sigma = \{\{\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i\}_{i=1}^\ell, \mathbf{a}_{ots}, \text{sig}\}$ ;
2. For  $i \in [1, \dots, \ell]$ , compute  $\mathbf{a}_i = \mathbf{a}'_i - \mathcal{H}_1(\mathbf{a}_{ots}) \bmod q$ ;
3. checks whether for each tuple of  $(\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i)$ ,  $\|\mathbf{r}_{i,0}\|, \|\mathbf{r}_{i,1}\| \leq B_1$  and  $\mathbf{b}_i \in D_{\mathbf{b}}$ ; outputs *reject* if not.
4. computes  $\mathbf{c}_i = \mathbf{r}_{i,0} + \mathbf{a}_i \mathbf{r}_{i,1} + \mathbf{h}_i \mathbf{b}_i$  for all  $i \in [1, \dots, \ell]$  and checks whether  $\mathbf{b}_1 \oplus \dots \oplus \mathbf{b}_\ell = \mathcal{H}(\mu, \mathbf{c}_1, \dots, \mathbf{c}_\ell)$ ; outputs *reject* if not.
5. verify  $\text{sig}$  is a signature for  $(\{\mathbf{r}_{i,0}, \mathbf{r}_{i,1}, \mathbf{b}_i\}_{i=1}^\ell, \{\mathbf{a}'_i\}_{i=1}^\ell, \mathbf{a}_{ots})$  with public key  $\mathbf{a}_{ots}$ ; outputs *reject* if fails.
6. outputs *accept*.

Note that in this implementation we use additions and subtractions over the  $\mathcal{R}_q$  instead of bit-wise XOR operations. Under the random oracle model  $\mathcal{H}_1(\mathbf{a}_{ots})$  will output a random ring element. This creates a perfect one-time mask that assures  $\mathbf{a}'$  is indistinguishable from random.

## 6.6 Known Attacks of Raptor

The NTRU assumption and the security of FALCON signature has been extensively studied in the literature [33, 19, 3, 22, 23, 27]. Here we consider the hardness of inverting the  $\text{CH}^+$ . We note that the attack described here does not work for the FALCON parameters. Indeed, this attack is strictly less efficient than forging a FALCON signature, or recovering the secret keys directly.

Our  $\text{CH}^+$  is defined as  $\mathbf{c} = \mathbf{r}_0 + \mathbf{a}\mathbf{r}_1 + \mathbf{h}\mathbf{b} \bmod q$ . Therefore, one may build a lattice with basis  $\begin{bmatrix} q\mathbf{I} \\ \mathbf{a} \ \mathbf{I} \\ \frac{1}{\alpha}\mathbf{h} \ 0 \ \frac{1}{\alpha}\mathbf{I} \end{bmatrix}$  where the vector  $(\mathbf{r}_0, \mathbf{r}_1, \alpha\mathbf{b})$  is a close vector to  $(\mathbf{c}, 0, 0)$ ;  $\alpha$  is a scaling factor of roughly  $\sim \eta$ . Note that solving the CVP here is not equivalent to finding a pre-image. Our  $\mathbf{b}$  is a binary vector, therefore, to have a successful forgery we will also require the third part of the output to be in the form of  $\alpha$  multiplying a binary vector.

It is easy to see that, even if we relax above the requirement, solving this CVP is still harder than forging a FALCON signature, i.e., solving some CVP for  $\begin{bmatrix} q\mathbf{I} \\ \mathbf{a} \ \mathbf{I} \end{bmatrix}$  where the root Hermite factor is a lot larger than that of attacks on the  $\text{CH}^+$  scheme.

## 6.7 Security Proof for Linkable Ring Signature Scheme

**Theorem 3 (Anonymity).** *Our linkable ring signature scheme is anonymous in random oracle model if the second requirement in section 3.1 holds for  $\text{CH}^+$ .*

*Proof.* Assume there is a simulator  $\mathcal{S}$  who plays  $\text{Game}_{\text{anon}}^*$  with adversary  $\mathcal{A}$  as follow:

*Setup.* Simulator  $\mathcal{S}$  runs  $\text{Setup}(1^\lambda) \rightarrow \text{param}$  and passes system parameter  $\text{param}$  to adversary  $\mathcal{A}$ .

*Oracle Simulation.* For registration oracle  $\mathcal{RO}(\perp)$ , when adversary queries  $\mathcal{RO}$ ,  $\mathcal{S}$  samples  $\text{pk}$  uniformly at random from its possible range.

*Challenge.*  $\mathcal{A}$  picks a list of user public keys  $L_{\text{pk}} = \{\text{pk}_1, \text{pk}_2, \dots, \text{pk}_\ell\}$  and a message  $\mu$ .  $\mathcal{A}$  sends  $(L_{\text{pk}}, \mu)$  to  $\mathcal{S}$ .  $\mathcal{S}$  randomly picks  $\pi \in \{1, \dots, \ell\}$ .  $\mathcal{S}$  also generates a pair of  $\Pi^{\text{OTS}}$  public key and secret key  $(\text{opk}_\pi, \text{osk}_\pi) \leftarrow \text{OKeygen}$  for  $\text{pk}_\pi$ . For  $i = \{1, \dots, \ell\}$ ,  $\mathcal{S}$  first computes  $\text{pk}'_i = \text{pk}_i \oplus \mathcal{H}_1(\text{opk}_\pi)$ . It also picks  $m_i, r_i$  and computes  $C_i = \text{Hash}(\text{pk}'_i, m_i, r_i)$ .  $\mathcal{S}$  programs  $\mathcal{H}_0(\mu, C_1, \dots, C_\ell, L_{\text{pk}}) = m_1 \oplus \dots \oplus m_\ell$ . Finally, it computes one-time signature  $\text{sig} = \text{OSign}(\text{osk}_\pi; (m_1, r_1), \dots, (m_\ell, r_\ell), L_{\text{pk}}, \text{opk}_\pi)$  and returns  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}_\pi, \text{sig}\}$  as signature.

For adversary  $\mathcal{A}$ ,  $\mathcal{A}$  can not distinguish this game from the original one. Since in the scheme, the signer public key  $\text{pk}_i$  is the result of the exclusive or of  $\text{hk}_i$  and  $\mathcal{H}_1(\text{opk}_i)$  where  $\mathcal{H}_1(\text{opk}_i)$  is a hash output. Thus,  $\mathcal{A}$  can not distinguish  $\text{pk}$  generated following the rule from  $\text{pk}$  sampled uniformly at random from its possible range.

**Case 1:** In case 1, we have the distribution of  $\text{hk}$  statistically close to uniform over  $R_{\text{hk}}$ . Thus for  $i = 1, \dots, \ell$ , all the  $\text{pk}'_i = \text{pk}_i \oplus \mathcal{H}_1(\text{opk}_\pi)$  are indistinguishable from a true hash key for  $\mathcal{A}$ . The best way for  $\mathcal{A}$  to win this game is to guess a  $\pi^* \in \{1, \dots, \ell\}$ . The probability for  $\pi^* = \pi$  is no more  $\frac{1}{\ell}$ .

**Case 2:** In case 2, we have the distribution of the distribution of  $\text{hk}$  computationally close to the uniform distribution and the probability for  $\text{hk} \leftarrow_{\mathcal{S}} R_{\text{hk}}$  and  $\text{hk}$  existing trapdoor is negligible. Thus for  $i = 1, \dots, \ell$ , all  $\text{pk}'_i = \text{pk}_i \oplus \mathcal{H}_1(\text{opk}_\pi)$  are computationally indistinguishable from a true hash key for  $\mathcal{A}$ . Since  $\text{pk}'_i$  can be considered as sampled uniformly at random from  $R_{\text{hk}}$ , the probability for  $\text{pk}'_i$

having trapdoor is negligible. Thus for  $\mathcal{A}$ , the best way winning this game is to guess a  $\pi^* \in \{1, \dots, \ell\}$ . The probability for  $\pi^* = \pi$  is no more  $\frac{1}{\ell}$ .

The advantage  $\text{adv}_{\mathcal{A}}^{\text{anon}}$  in this game is negligible. Our scheme is anonymous.

**Theorem 4 (Linkability).** *Our linkable ring signature is linkable in random oracle model if  $\text{CH}^+$  is collision resistant.*

*Proof.* Assume there is an adversary  $\mathcal{A}$  who can successfully forge a linkable ring signature with probability  $\delta$  by making at most  $q_r$  queries to  $\mathcal{RO}$  oracle,  $q_c$  queries to  $\mathcal{CO}$  oracle,  $q_s$  queries to  $\mathcal{SO}$  oracle, and  $q_h$  queries to random oracle  $\mathcal{H}_0$ . We define the number of possible values in the output range of  $\mathcal{H}_0$  as  $|\mathcal{D}_{\mathcal{H}}|$ . Then we can construct a simulator  $\mathcal{S}$  who can break the collision resistance of  $\text{CH}^+$  with a non-negligible probability.

$\mathcal{S}$  is given an instance as following: Given  $\text{CH}^+$  hash key  $\text{hk}_c$  and  $\text{CH}^+$  parameter  $\text{param}_c^{\text{ch}}$ , it is asked to output  $\{(m', r'), (m'', r'')\}$  such that  $(m', r') \neq (m'', r'')$  and  $\text{Hash}(\text{hk}_c, m', r') = \text{Hash}(\text{hk}_c, m'', r'')$  for  $\text{param}_c^{\text{ch}}$ . In order to use  $\mathcal{A}$  to solve this problem instance, the simulator  $\mathcal{S}$  needs to simulate the challenger  $\mathcal{C}$  and oracles to play  $\text{Game}_{\text{forge}}$  with  $\mathcal{A}$ .  $\mathcal{S}$  runs as follow:

*Setup.* Simulator  $\mathcal{S}$  picks two hash functions  $\mathcal{H}_0, \mathcal{H}_1$  and sets as system parameter.  $\mathcal{H}_0$  will be modeled as random oracle.  $\mathcal{S}$  picks random coins  $\psi, \phi$  for  $\mathcal{S}$  and  $\mathcal{A}$  respectively. Besides,  $\mathcal{S}$  also picks  $\{h_1, h_2, \dots, h_p\} \xleftarrow{\$} \mathcal{D}_{\mathcal{H}_0}$  as the  $q_h$  responses of the random oracle  $\mathcal{H}_0$  and  $\mathcal{S}$  also picks  $\{h'_1, h'_2, \dots, h'_t\} \xleftarrow{\$} \mathcal{D}_{\mathcal{H}_1}$  as the  $q'_h$  responses of the random oracle  $\mathcal{H}_1$ .  $\mathcal{S}$  gives random coin  $\phi$  to  $\mathcal{A}$ .  $\mathcal{S}$  sets  $\mathcal{H}_0, \mathcal{H}_1, \text{param}_c^{\text{ch}}$  as public parameter.

*Oracle Simulation.*  $\mathcal{S}$  simulates the oracles as follow:

- $\mathcal{RO}(\perp)$ : Assume adversary  $\mathcal{A}$  can only queries  $\mathcal{RO}$   $q_r$  times ( $q_r \geq 1$ ).  $\mathcal{A}$  random picks an index  $\mathcal{I} \xleftarrow{\$} [1, \dots, q_r]$ . For index  $\mathcal{I}$ ,  $\mathcal{S}$  sets  $\text{pk}_{\mathcal{I}} = \text{hk}_{\mathcal{I}} = \text{hk}_c \oplus h'_{\mathcal{Q}}$  where  $h'_{\mathcal{Q}} \xleftarrow{\$} \{h'_1, h'_2, \dots, h'_t\}$ . For other index,  $\mathcal{S}$  generates the public key and secret key according to the **KeyGen** algorithm where the output of the random oracle  $\mathcal{H}_1$  will be the first  $h'_i \in \{h'_1, h'_2, \dots, h'_t\}$  that has not been used yet. Upon the  $j$ th query,  $\mathcal{S}$  returns the corresponding public key.
- $\mathcal{CO}(\text{pk})$ : On input a public key  $\text{pk}$  returned by  $\mathcal{RO}$  oracle,  $\mathcal{S}$  first checks whether it corresponds to index  $\mathcal{I}$ . If yes,  $\mathcal{S}$  aborts. Otherwise,  $\mathcal{S}$  returns the corresponding secret key  $\text{sk}$ . According to the requirements,  $\mathcal{A}$  is allowed to query this oracle no more than  $k - 1$  times.
- $\mathcal{SO}(\mu, L_{\text{pk}}, \text{pk}_{\pi})$ : When  $\mathcal{A}$  queries  $\mathcal{SO}$  on message  $\mu$ , a list of public keys  $L_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_{\ell}\}$  and the public key for the signer  $\text{pk}_{\pi}$  where  $\text{pk}_{\pi} \in L_{\text{pk}}$ ,  $\mathcal{S}$  simulates  $\mathcal{SO}$  as follow:
  - If  $\text{pk}_{\pi} \neq \text{pk}_{\mathcal{I}}$ ,  $\mathcal{S}$  runs **Signing**( $\text{sk}_{\pi}, \mu, L_{\text{pk}}$ ) where the output of the random oracle  $\mathcal{H}_0$  will be the first  $h_i \in \{h_1, h_2, \dots, h_p\}$  that has not been used yet.  $\mathcal{S}$  returns the signature  $\sigma$  to  $\mathcal{A}$ ;
  - If  $\text{pk}_{\pi} = \text{pk}_{\mathcal{I}}$ , for  $i \in [1, \dots, \ell]$ ,  $\text{pk}_i = \text{hk}'_i$ ,  $\mathcal{S}$  runs **OKeygen**( $1^{\lambda}$ )  $\rightarrow$  ( $\text{opk}_{\pi}, \text{osk}_{\pi}$ ) and programs  $\mathcal{H}_1(\text{opk}_{\pi})$  as the first  $h'_i \in \{h'_1, h'_2, \dots, h'_t\}$  that has not been used yet. computes  $\text{hk}_i = \mathcal{H}_1(\text{opk}_{\pi}) \oplus \text{hk}'_i$  for  $i \in$

$[1, \dots, \ell]$ .  $\mathcal{S}$  samples  $m_i, r_i$  and computes  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ .  $\mathcal{S}$  then programs random oracle  $\mathcal{H}_0$  as  $\mathcal{H}_0(\mu, C_1, \dots, C_\ell, L_{\text{pk}}) = m_1 \oplus \dots \oplus m_\ell$ .  $\mathcal{S}$  also computes one-time signature  $\text{sig} = \text{OSign}(\text{osk}_\pi; (m_1, r_1), \dots, (m_\ell, r_\ell), L_{\text{pk}}, \text{opk})$ .  $\mathcal{S}$  returns signature  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}_\pi, \text{sig}\}$ .

- *Random Oracle  $\mathcal{H}_0$  ( $\mathcal{H}_1$ )*: For query input that has already been programmed,  $\mathcal{S}$  returns the corresponding output. Otherwise, the output of the random oracle will be the first  $h_i \in \{h_1, h_2, \dots, h_p\}$  ( $h'_i \in \{h'_1, \dots, h'_t\}$ ) that has not been used yet.  $\mathcal{S}$  will record all the queries to the random oracle in a table, in case same query is issued twice.

*Output.* Adversary  $\mathcal{A}$  outputs  $k$  sets  $\{L_{\text{pk}}^{(i)}, \mu_i, \sigma_i\}$  for  $i \in [1, \dots, k]$ . These  $k$  sets should satisfy that **Verification** $(\mu_i, \sigma_i, L_{\text{pk}}^{(i)}) = \text{accept}$ ;  $\mathcal{A}$  queried  $\mathcal{CO}$  less than  $k$  times; and **Link** $(\sigma_i, \sigma_j, \mu_i, \mu_j, L_{\text{pk}}^{(i)}, L_{\text{pk}}^{(j)}) = \text{unlinked}$  for  $i \neq j$  and  $i, j \in [1, \dots, k]$ . Since  $\mathcal{A}$  is allowed query  $\mathcal{CO}$  less than  $k$  times. At least one of the output signatures should be generated from the secret key that  $\mathcal{A}$  does not obtain. Assume  $\sigma_j, j \in \{1, \dots, k\}$  is not produced by the secret key  $\mathcal{A}$  obtaining. If  $\text{pk}_{\mathcal{I}} \notin L_{\text{pk}}^{(j)}$  and  $H_1(\text{opk}_j) = h'_{\mathcal{Q}}$ , abort.

The probability for  $\text{pk}_{\mathcal{I}} \in L_{\text{pk}}^{(j)}$  is no less than  $\frac{1}{q_r}$  and the probability for  $H_1(\text{opk}_j) = h'_{\mathcal{Q}}$  is no less than  $\frac{1}{q_h}$ . In the following we use  $(\mu^*, \sigma^*, L_{\text{pk}}^*)$  to denote  $(\mu^j, \sigma^j, L_{\text{pk}}^{(j)})$ . Simulator  $\mathcal{S}$  then uses the set  $(\mu^*, \sigma^*, L_{\text{pk}}^*)$  to break the collision resistance of  $\text{CH}^+$ .  $\mathcal{S}$  phrases  $\sigma^*$  to  $\{(m_1^*, r_1^*), \dots, (m_\ell^*, r_\ell^*), \text{opk}^*, \text{sig}^*\}$  and denotes  $m_1^* \oplus \dots \oplus m_\ell^*$  by  $h^*$ . Notice that with probability  $1 - \frac{1}{|\mathcal{D}_{\mathcal{H}}|}$ ,  $h^*$  will be one of the  $h_i \in \{h_1, \dots, h_p\}$  or the hash outputs from the  $\mathcal{SO}$  queries. Since if the random oracle was not queried or programmed on some input, the probability for  $\mathcal{A}$  to produce a  $\{(m_1^*, r_1^*), \dots, (m_\ell^*, r_\ell^*)\}$  such that  $m_1^* \oplus \dots \oplus m_\ell^* = \mathcal{H}(\mu^*, C_1^*, \dots, C_\ell^*, L_{\text{pk}}^*)$  is  $\frac{1}{|\mathcal{D}_{\mathcal{H}}|}$ . The probability for  $\mathcal{A}$  to produce a forgery is  $\delta$ . Thus, the probability for  $\mathcal{A}$  outputs a forgery  $(\mu^*, \sigma^*, L_{\text{pk}}^*)$  and  $h^* = \mathcal{H}_0(\mu^*, C_1^*, \dots, C_\ell^*, L_{\text{pk}}^*)$  has been queried in  $\mathcal{SO}$  or  $\mathcal{RO}$  is  $\delta - \frac{1}{|\mathcal{D}_{\mathcal{H}}|}$ .

**Type 1 forgery:** The first type of forgery is that, for the forgery  $(\mu^*, \sigma^* = \{(m_1^*, r_1^*), \dots, (m_\ell^*, r_\ell^*), \text{opk}^*, \text{sig}^*\}, L_{\text{pk}}^*)$ ,  $m_1^* \oplus \dots \oplus m_\ell^* = \mathcal{H}(\mu^*, C_1^*, \dots, C_\ell^*, L_{\text{pk}}^*)$  is a response of random oracle  $\mathcal{H}_0$  on  $\mathcal{H}_0(\mu', C'_1, \dots, C'_\ell, L'_{\text{pk}})$  during a  $\mathcal{SO}$  query. Then, we have

$$\mathcal{H}_0(\mu^*, C_1^*, \dots, C_\ell^*, L_{\text{pk}}^*) = \mathcal{H}_0(\mu', C'_1, \dots, C'_\ell, L'_{\text{pk}})$$

If  $\mu^* \neq \mu'$ ,  $(C_1^*, \dots, C_\ell^*) \neq (C'_1, \dots, C'_\ell)$  or  $L'_{\text{pk}} \neq L_{\text{pk}}^*$ , we find a collision of the hash function. Thus, we must have  $\mu^* = \mu'$ ,  $(C_1^*, \dots, C_\ell^*) = (C'_1, \dots, C'_\ell)$  and  $L'_{\text{pk}} = L_{\text{pk}}^*$ . Since we require that  $(\mu^*, L_{\text{pk}}^*)$  has not been queried by  $\mathcal{A}$  for signature. Type 1 forgery is not a valid forgery.

**Type 2 forgery:** The second type of forgery is that,  $h^* = m_1^* \oplus \dots \oplus m_\ell^*$  is a response of a  $\mathcal{RO}$  query issued by  $\mathcal{A}$ . We store the forgery  $(\mu^*, \sigma^* = \{(m_1^*, r_1^*), \dots, (m_\ell^*, r_\ell^*), \text{opk}^*, \text{sig}^*\}, L_{\text{pk}}^*)$ . Assume  $h^* = h_i$  where  $h_i \in \{h_1, \dots, h_p\}$ , picks new  $h''_i, \dots, h''_p \xleftarrow{\$} D_H$ .  $\mathcal{S}$  then run  $\text{Game}_{\text{forge}}$  again on  $(\text{hk}_c, \text{param}_{\text{c}}^{\text{ch}}, \psi, \phi, h_1, \dots, h_{i-1}, h''_i, \dots, h''_p)$ . According to the General Forking Lemma, we obtain that

$h_i'' \neq h_i$  and the adversary  $\mathcal{A}$  uses the random oracle response  $h_i''$  in its forgery is at least

$$\Pr = \text{acc} \left( \frac{\text{acc}}{q_s + q_h} - \frac{1}{|\mathcal{D}_{\mathcal{H}}|} \right),$$

where  $\text{acc} = (1 - \frac{1}{q_r}) \frac{1}{q_r \cdot q_h'} (\delta - \frac{1}{|\mathcal{D}_{\mathcal{H}}|})$ . Which means that with the same probability,  $\mathcal{A}$  will output a forgery  $\{\mu', \sigma' = \{(m'_1, r'_1), \dots, (m_{\ell'}, r_{\ell'}), \text{opk}', \text{sig}'\}, L'_{\text{pk}}\}$  and  $\mu^* = \mu', (C_1^*, \dots, C_{\ell'}^*) = (C'_1, \dots, C'_{\ell'}), L'_{\text{pk}} = L_{\text{pk}}^*$ , and  $\text{opk}' = \text{opk}^*$ . Thus,  $\ell = \ell'$ . At least with probability  $\frac{1}{\ell}$ ,  $m_{\mathcal{I}}^* \neq m'_{\mathcal{I}}$ . Since  $C_{\mathcal{I}}^* = C'_{\mathcal{I}}$ ,  $\mathcal{S}$  has  $\text{Hash}(\text{hk}_c, m_{\mathcal{I}}^*, r_{\mathcal{I}}^*) = \text{Hash}(\text{hk}_c, m'_{\mathcal{I}}, r'_{\mathcal{I}})$ .  $(m_{\mathcal{I}}^*, r_{\mathcal{I}}^*)$  and  $(m'_{\mathcal{I}}, r'_{\mathcal{I}})$  is a collision for hash key  $\text{hk}_c$ .

The probability for  $\mathcal{S}$  aborting during  $\mathcal{CO}$  is no more than  $\frac{1}{q_r}$ . The probability for  $\mathcal{S}$  not aborting during *output* is no less than  $\frac{1}{q_r} \cdot \frac{1}{q_h}$ . Thus, the probability for  $\mathcal{S}$  solving problem instance is no less than  $(1 - \frac{1}{q_r}) \frac{1}{q_r \cdot q_h'} \cdot \Pr$  which is non-negligible.

**Theorem 5 (Nonslanderability).** *Our linkable ring signature is nonslanderable in random oracle model if the one-time signature scheme  $\Pi^{OTS}$  is one-time unforgeable.*

*Proof.* Assume there is an adversary  $\mathcal{A}$  who can win  $\text{Game}_{\text{slander}}$  with probability  $\delta$ . Then we can construct a simulator  $\mathcal{S}$  who can break the unforgeability of the one-time signature  $\Pi^{OTS}$  used in our construction also with probability  $\delta$ .

$\mathcal{S}$  is given a  $\Pi^{OTS}$  public key  $\text{opk}'$  and is allowed to query the signature  $\text{sig}'$  of a message  $m'$  once for any message of its choosing.  $\mathcal{S}$  is said breaking the unforgeability of  $\Pi^{OTS}$  if it can produce  $(m'', \text{sig}'')$  such that  $(m'', \text{sig}'') \neq (m', \text{sig}')$  and  $\text{Over}(\text{opk}'; \text{sig}''; m'') = \text{accept}$ . In order to use  $\mathcal{A}$  to break the unforgeability of  $\Pi^{OTS}$ , the simulator  $\mathcal{S}$  needs to simulate the challenger  $\mathcal{C}$  and oracles to play  $\text{Game}_{\text{slander}}$  with  $\mathcal{A}$ .  $\mathcal{S}$  runs as follow:

*Setup.* Simulator  $\mathcal{S}$  picks two hash functions  $\mathcal{H}_0, \mathcal{H}_1$ . It also generates  $\text{param}^{\text{ch}} \leftarrow \text{SetUp}(1^\lambda)$ .  $\mathcal{H}_0, \mathcal{H}_1, \text{param}^{\text{ch}}$  and  $\Pi^{OTS}$  will be set as system parameter.  $\mathcal{H}_0$  and  $\mathcal{H}_1$  will be modeled as random oracles.

*Oracle Simulation.*  $\mathcal{S}$  simulates the oracles as follow:

- $\mathcal{RO}(\perp)$ :  $\mathcal{S}$  uniformly samples  $\text{hk}'$  and returns  $\text{hk}'$  as the public key.
- $\mathcal{CO}(\text{pk})$ : On input a public key  $\text{pk} = \text{hk}'$  returned by  $\mathcal{RO}$  oracle,  $\mathcal{S}$  first checks whether it is an output of  $\mathcal{RO}$  query. If yes,  $\mathcal{S}$  runs  $\text{OKeygen}(1^\lambda) \rightarrow (\text{opk}, \text{osk})$ .  $\mathcal{S}$  runs  $\text{TrapGen}(1^\lambda) \rightarrow (\text{hk}, \text{tr})$ .  $\mathcal{S}$  returns  $(\text{tr}, \text{opk}, \text{osk})$  as secret key and programs  $\mathcal{H}_1(\text{opk}) = \text{hk} \oplus \text{hk}'$ .
- $\mathcal{SO}(\mu, L_{\text{pk}}, \text{pk}_\pi)$ : When  $\mathcal{A}$  queries  $\mathcal{SO}$  on message  $\mu$ , a list of public keys  $L_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_\ell\}$  and the public key for the signer  $\text{pk}_\pi$  where  $\text{pk}_\pi = \text{hk}' \in L_{\text{pk}}$ ,  $\mathcal{S}$  simulates  $\mathcal{SO}$  as follow:
  - If  $\text{pk}_\pi$  has been queried to  $\mathcal{CO}$  oracle,  $\mathcal{S}$  runs  $\text{Signing}(\text{sk}_\pi, \mu, L_{\text{pk}})$  and returns the signature  $\sigma$  to  $\mathcal{A}$ ;
  - If  $\text{pk}_\pi$  has not been queried to  $\mathcal{CO}$ ,  $\mathcal{S}$  runs  $\text{OKeygen}(1^\lambda) \rightarrow (\text{opk}, \text{osk})$ . For  $i \in [1, \dots, \ell]$ ,  $\text{pk}_i = \text{hk}'_i$ ,  $\mathcal{S}$  computes  $\text{hk}_i = \text{hk}'_i \oplus \mathcal{H}_1(\text{opk})$ .  $\mathcal{S}$  samples  $m_i, r_i$  and computes  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ .  $\mathcal{S}$  then programs random oracle  $\mathcal{H}_0$  as  $\mathcal{H}_0(\mu, C_1, \dots, C_\ell, L_{\text{pk}}) = m_1 \oplus \dots \oplus m_\ell$ .  $\mathcal{S}$  Computes

- one-time signature  $sig = \text{OSign}(\text{osk}; (m_1, r_1), \dots, (m_\ell, r_\ell), L_{\text{pk}}, \text{opk})$ .  $\mathcal{S}$  returns signature  $\sigma = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}, sig\}$ .
- *Random Oracle  $\mathcal{H}_0$* : For input that has already been programmed,  $\mathcal{S}$  returns the corresponding output. Otherwise,  $\mathcal{S}$  randomly samples  $h_0$  and outputs  $h_0$ .  $\mathcal{S}$  will record all the queries to the random oracle in a table, in case same query is issued twice.
  - *Random Oracle  $\mathcal{H}_1$* : For input that has already been programmed,  $\mathcal{S}$  returns the programmed output. Otherwise,  $\mathcal{S}$  randomly samples  $h_1$  and output  $h_1$ .  $\mathcal{S}$  will record all the queries to the random oracle in a table, in case same query is issued twice.

*Challenge.*  $\mathcal{A}$  sends a list of public keys  $L'_{\text{pk}} = \{\text{pk}_1, \dots, \text{pk}_\ell\}$ , message  $\mu$  and public key  $\text{pk}_\pi \in L_{\text{pk}}$ . According to the requirements,  $\text{pk}_\pi$  should not be queried to  $\mathcal{CO}$  or as an insider to  $\mathcal{SO}$ . Thus, there is no one-time signature keys chosen for  $\text{pk}_\pi$  yet.  $\mathcal{S}$  takes  $\text{opk}'$  as the one-time signature public key for  $\text{pk}_\pi$ . For  $i \in [1, \dots, \ell]$ ,  $\text{pk}_i = \text{hk}'_i$ ,  $\mathcal{S}$  computes  $\text{hk}_i = \text{hk}'_i \oplus \mathcal{H}_1(\text{opk}')$ .  $\mathcal{S}$  samples  $m_i, r_i$  and computes  $C_i = \text{Hash}(\text{hk}_i, m_i, r_i)$ .  $\mathcal{S}$  then programs random oracle  $\mathcal{H}_0$  as  $\mathcal{H}_0(\mu, C_1, \dots, C_\ell, L_{\text{pk}}) = m_1 \oplus \dots \oplus m_\ell$ . Then,  $\mathcal{S}$  queries for the one-time signature  $sig'$  of message  $\nu' = \{(m_1, r_1), \dots, (m_\ell, r_\ell), L'_{\text{pk}}, \text{opk}'\}$ .  $\mathcal{S}$  returns  $\sigma' = \{(m_1, r_1), \dots, (m_\ell, r_\ell), \text{opk}', sig'\}$  to  $\mathcal{A}$ .

*Output.*  $\mathcal{A}$  outputs a list of public keys  $L_{\text{pk}}^*$ , message  $\mu^*$ , and a signature  $\sigma^*$  such that **Verification** $(\mu^*, \sigma^*, L_{\text{pk}}^*) = \text{accept}$ , **Link** $(\sigma, \sigma^*, \mu, \mu^*, L'_{\text{pk}}, L_{\text{pk}}^*) = \text{linked}$ .

Simulator  $\mathcal{S}$  then use  $(L_{\text{pk}}^*, \mu^*, \sigma^*)$  to break the unforgeability of  $\Pi^{OTS}$ .  $\mathcal{S}$  phrases  $\sigma^* = \{(m_1^*, r_1^*), \dots, (m_{\ell'}^*, r_{\ell'}^*), \text{opk}^*, sig^*\}$ . Since **Link** $(\sigma, \sigma^*, \mu, \mu^*, L'_{\text{pk}}, L_{\text{pk}}^*) = \text{linked}$ , we must have  $\text{opk}' = \text{opk}^*$  and **Over** $(\text{opk}^*; sig^*; (m_1^*, r_1^*), \dots, (m_{\ell'}^*, r_{\ell'}^*), L_{\text{pk}}^*, \text{opk}^*) = \text{accept}$ . Since  $\sigma^*, L_{\text{pk}}^*$  must be different from  $\sigma', L'_{\text{pk}}$ .  $\mathcal{S}$  obtains a one-time message signature pair where message is  $\nu^* = \{(m_1^*, r_1^*), \dots, (m_{\ell'}^*, r_{\ell'}^*), L_{\text{pk}}^*, \text{opk}^*\} \neq \nu'$  in challenge.  $sig^*$  is a valid one-time signature for  $\text{opk}'$  and  $\nu^*$ .  $\mathcal{S}$  breaks the unforgeability of  $\Pi^{OTS}$ .

According to Theorem 2, our linkable ring signature scheme has nonsladerability and linkability. Thus, it is also unforgeable.

For the two security requirements of our ring signature scheme, both of them achieve the strongest security notions. Specifically, the unforgeability of our ring signature scheme allows chosen key attack to the signing oracle and chosen subring attack to the target signature. The anonymity of our ring signature scheme is unconditional and allows chosen key attack. For our linkable ring signature scheme, the unforgeability and linkability allows chosen key attack to the signing oracle and chosen subring attack to the target signature. The scheme is anonymous under chosen subring attack and the slanderability of our linkable ring signature scheme allows chosen key attack.
