# Dual-Mode NIZKs: Possibility and Impossibility Results for Property Transfer

VIVEK ARTE<sup>1</sup>

MIHIR BELLARE<sup>2</sup>

February 2021

## Abstract

This paper formulates, and studies, the problem of property transference in dual-mode NIZKs. We say that a property  $P$  (such as soundness, ZK or WI) transfers, if, one of the modes having  $P$  allows us to prove that the other mode has the computational analogue of  $P$ , as a consequence of nothing but the indistinguishability of the CRSs in the two modes. Our most interesting finding is negative; we show by counter-example that the form of soundness that seems most important for applications fails to transfer. On the positive side, we develop a general framework that allows us to show that zero knowledge, witness indistinguishability, extractability and weaker forms of soundness do transfer. Our treatment covers conventional, designated-verifier and designated-prover NIZKs in a unified way.

# 1 Introduction

Non-interactive zero-knowledge (NIZK) systems [BFM88, BDSMP91] are blossoming. New applications are fueling the development of schemes that are not only more efficient than classical ones but may also be simpler, more elegant and more powerful in application. One way this happens is via the concept of dual mode [GOS06b, GOS06a, GOS12, AFH<sup>+</sup>16, HU19, LPWW20].

BACKGROUND. Groth, Ostrovsky and Sahai [GOS06b, GOS06a, GOS12] build a pair of NIZK systems  $\Pi_0, \Pi_1$  such that (1) the prover and verifier are the same for both (2) the two systems have CRSs that, although different, are computationally indistinguishable under the SubGroup Decision or Decision Linear Assumptions, and (3)  $\Pi_0$  has perfect soundness while  $\Pi_1$  has perfect zero-knowledge (ZK).

Why do this? GOS wanted a (single) NIZK system that was perfect ZK and computationally sound. The claim would be that  $\Pi_1$  has these properties, because CRS indistinguishability, plus the perfect soundness of  $\Pi_0$ , would automatically imply computational soundness of  $\Pi_1$ . In our language, soundness has been “transferred” from  $\Pi_0$  to  $\Pi_1$ , as a consequence of nothing but CRS indistinguishability.

Recognition of the power of this technique lead to the formalization of dual-mode systems. Rather than a single or accepted definition, however, there are many, with a common core and varying peripherals [AFH<sup>+</sup>16, HU19, LPWW20]. At its core, a dual-mode system  $D\Pi$  has a CRS generator that takes an input  $\mu \in \{0, 1\}$  (the desired mode), and the CRSs generated in the two modes must be computationally indistinguishable. Proving and verification algorithms are as in a (single mode) NIZK system. The modes are called binding and hiding, and the (varying) peripheral requirements placed on them in prior works are summarized in [Figure 1](#).

Looking across usage and applications in the literature, the value of dual-mode continues to lie in transference, namely, being able to prove that if a property (like soundness) is present in one mode then its computational analogue is also present in the other, as a consequence just of the indistinguishability of the CRSs in the two modes. But there is growing recognition that transference can be subtle and not as simple as it seems. For example, certain (weaker) forms of soundness are proven to transfer, but for other (stronger) forms, the natural proof approach fails, and whether or not the transference holds remains an open question [GOS12, LPWW20]. This lead GOS, in the journal version of their work [GOS12], to introduce culpable soundness, an intermediate notion that they could show transfers.

OVERVIEW OF OUR CONTRIBUTIONS. We want to understand the limitations and possibilities of transference, including which properties transfer, which don’t, and why. We divide our contributions into the following parts.

▷ **Definitions.** We start by defining a dual-mode system  $D\Pi$  in a different way; we ask *only* for the (core) CRS indistinguishability requirement. Unlike prior works (cf. [Figure 1](#)), no requirements are placed on the individual modes. We then define, in the natural way, the (single-mode) systems  $D\Pi_0, D\Pi_1$  induced by  $D\Pi$ . A property  $P$  (soundness, ZK, WI, ...) is a requirement on a single-mode system, not a dual-mode one. Transference of a property  $P$  is now the question: If  $D\Pi_\mu$  satisfies  $P$ , does  $D\Pi_{1-\mu}$  satisfy the computational analogue of  $P$ ?

▷ **Negative results.** We show that certain strong (desirable, application-enabling) forms of soundness fail to transfer. These negative results are established by giving explicit counter-examples under standard assumptions (CDH, DDH). This shows that the difficulties noted in prior work with regard to proving transference for certain forms of soundness [GOS12, LPWW20], are inherent.

▷ **Positive results.** We formalize a “property”  $P$  as a *property specification*  $PS$  and give sufficient conditions on  $PS$  for it to successfully transfer. Through this we show that ZK, WI and

Who	Requirements for mode 0	Requirements for mode 1
[AFH <sup>+</sup> 16]	perfect soundness and extractability	perfect ZK and WI
[HU19]	statistical soundness and extractability	statistical WI
[LPWW20]	statistical soundness	statistical ZK
<b>Our work</b>	<b>None</b>	<b>None</b>

Figure 1: Requirements placed on the two modes in definitions of dual-mode systems.

extractability (we define them in strong ways that are application-enabling) do transfer, as do weaker (as per what follows, not application-enabling) forms of soundness. Our framework may have future value in helping evaluate or establish transference of the many definitional variants of the basic properties that arise.

▷ **Applicability assessment.** It is desirable that the forms of soundness that transfer be suitable for applications, leading us to ask, which are? We examine a canonical application of NIZKs, the one to digital signatures [BG90, CDG<sup>+</sup>17], and find that the form of soundness it needs is one that our negative results show does not transfer. Thus, our finding is that the most application-enabling (stronger, desirable) forms of soundness fail to transfer, while weaker forms do transfer.

▷ **Unified treatment.** We define single and dual-mode systems in a way that includes, as special cases, the conventional [BFM88, BDSMP91], designated verifier [ES02, PsV06, DFN06] and designated prover [KW18, KNY19] settings. Our definition of CRS indistinguishability asks that it hold even when the adversary knows the proving and verification keys (if any). Soundness is required even in the presence of a verification oracle, to capture the reusable designated verifier setting [LPWW20]. Our results apply to all these settings. The motivation for this broad treatment is the many recent advances in settings beyond the conventional one [KW18, KNY19, LPWW20, BCGI18, BCG<sup>+</sup>19]. In the rest of this Introduction, however, we will for simplicity confine discussion to the conventional setting.

DEFINITIONS. Recall that the syntax of a (classical, single-mode) NIZK system specifies three polynomial-time algorithms: CRS-generator  $\Pi.C$  that produces the common reference string  $\text{crs} \leftarrow_s \Pi.C(1^\lambda)$  from the (unary representation of the) security parameter  $\lambda$ ; proof-generator  $\Pi.P$  that produces the proof  $\text{pf} \leftarrow_s \Pi.P(1^\lambda, \text{crs}, x, w)$  from an instance  $x$  and witness  $w$ ; and verifier  $\Pi.V$  that produces a boolean decision  $d \leftarrow \Pi.V(1^\lambda, \text{crs}, x, \text{pf})$  for a candidate proof  $\text{pf}$ . For such systems, one can consider many security properties, including soundness, extractability, zero-knowledge and witness indistinguishability. But each property has many variant forms (statistical, perfect, non-adaptive, adaptive, single or multi-theorem, ...), and, even within these, differences in definitional details, so that in the end there is a veritable zoo of notions.

We define a dual-mode proof system  $D\Pi$  to have the same syntax as a (single-mode) proof system except that the CRS generator  $D\Pi.C$  takes an additional input  $\mu \in \{0, 1\}$ , the desired mode. (Prover algorithm  $D\Pi.P$  and verifier algorithm  $D\Pi.V$  remain as before.) The only semantic requirement is mode indistinguishability, asking that the CRSs generated in modes 0, 1 be computationally indistinguishable.

Next we define the induced (single-mode) proof systems  $D\Pi_0$  and  $D\Pi_1$ . For both, the prover algorithm is  $D\Pi.P$  and the verifier algorithms is  $D\Pi.V$ . The difference is their CRS generation algorithms, that of  $D\Pi_\mu$  being  $D\Pi.C$  with the mode input set to  $\mu \in \{0, 1\}$ . Since the induced proof systems are single-mode ones, one can speak of their having, or not having, a property  $P$  from the

list above. Transference for a property  $P$  is now the following question: If  $D\Pi_\mu$  satisfies  $P$ , does  $D\Pi_{1-\mu}$  also satisfy  $P$ ?

TRANSFERENCE INTUITION. One would imagine that any property  $P$  transfers, by the following proof. Suppose  $P$  holds for one mode, wlog  $D\Pi_0$ . We want to show it also holds in  $D\Pi_1$ . Let  $A$  be a PT (polynomial-time) adversary violating  $P$  in  $D\Pi_1$ . We build a PT adversary  $D$  violating mode indistinguishability. As per the definition of the game for the latter, the input to  $D$  is a crs of a challenge mode  $\mu \leftarrow_s \{0, 1\}$ , and  $D$  is trying to determine  $\mu$ . Adversary  $D$  runs  $A$  on input crs and *tests if it violates*  $P$ . If so, it predicts that  $\mu = 1$ , else that  $\mu = 0$ . The difficulty is that “testing whether  $A$  violates  $P$ ” may not be doable in polynomial-time. In particular, for soundness (depending on the precise definition of the property as we consider below), it may involve testing membership in the underlying language, which, for languages of interest, is not doable in polynomial-time. This difficulty is recognized [GOS12, LPWW20]. However, it does not mean that the property necessarily fails to transfer; it just means that the obvious proof approach fails. Is there another, more clever one, that succeeds? We will answer this question negatively, giving counterexamples to show non-transference for certain properties of interest in applications.

SOUNDNESS NOTIONS. The underlying **NP**-relation  $R$  defines a language  $L_R(\text{crs})$ . (As per [Gro06], and to cover systems in the literature, the language is allowed to depend on the CRS.) Soundness of a (single-mode) proof system  $\Pi$  for  $R$  asks that an adversary given crs be unable to find an  $x \notin L_R(\text{crs})$ , and a proof  $\text{pf}$ , such that  $\Pi.V(1^\lambda, \text{crs}, x, \text{pf}) = \text{true}$ . The difficulty, for transference, is that testing whether the adversary wins seems to require testing that  $x \notin L_R(\text{crs})$ , which is likely not doable in PT. With attention drawn to this issue, however, one sees that whether or not the test is required depends on exactly how the soundness game is defined. The broad format is that the game picks and gives crs to the adversary, who then provides the game with  $x, \text{pf}$ , and the game then performs a “winning test.” Now we consider two definitions: SND-P (penalty style) and SND-E (exclusion style). (This follows the consideration of similar notions for IND-CCA encryption in [BHK15].) In SND-P, the winning test is that  $x \notin L_R(\text{crs})$  and  $\Pi.V(1^\lambda, \text{crs}, x, \text{pf}) = \text{true}$ , and SND-P security asks that any PT adversary has negligible winning probability. In SND-E the winning test is just that  $\Pi.V(1^\lambda, \text{crs}, x, \text{pf}) = \text{true}$ , and SND-E security asks for negligible winning probability, not for all adversaries, but for a subclass we call membership conscious: the probability that the  $x$  they provide is in  $L_R(\text{crs})$  is negligible. (Membership consciousness is an assumption on the adversary. Nothing in the game verifies it.) Clearly, SND-P is stronger:  $\text{SND-P} \Rightarrow \text{SND-E}$ . (Any SND-P secure  $\Pi$  is also SND-E secure.) We can show that SND-E is strictly weaker:  $\text{SND-E} \not\Rightarrow \text{SND-P}$ . (There exists a  $\Pi$  that is SND-E secure but not SND-P secure.)

SOUNDNESS TRANSFERENCE. We show that (1) SND-E transfers, but (2) SND-P does not. The first follows from general results we discuss below. With regard to the second, that the winning test is not PT is an indication that transfer may fail, but not a proof that it does. (What it means is that the particular, above-discussed approach to prove transference fails.) In Theorem 4.4, we show non-transference via a counter-example. We give a dual-mode proof system  $D\Pi$  and relation  $R$  such that (2a)  $D\Pi$  satisfies mode indistinguishability (2b)  $D\Pi_1$  satisfies SND-P for  $R$  but (2c)  $D\Pi_0$  does *not* satisfy SND-P for  $R$ . These results assume hardness of the DDH (Decision Diffie-Hellman) problem in an underlying group. We show (2a) and (2b) by reductions to the assumed hardness of DDH. We show (2c) by an attack, a description of an explicit PT adversary that, with probability one, violates SND-P for  $D\Pi_0$ .

PENALTY OR EXCLUSION? The lack of transference of SND-P is more than an intellectual curiosity; it inhibits applicability. We consider building digital signatures from NIZKs, a canonical application that originates in [BG90], and, with [CDG<sup>+</sup>17], is seeing renewed interest as a way to obtain efficient

post-quantum signatures. We look closely at the proof to see that while SND-P suffices, SND-E does not appear to do so. This phenomenon seems fairly general: applications of NIZKs that rely on soundness seem to need SND-P, not SND-E.

TRANSFERENCE FRAMEWORK. We turn to positive results, proving that certain (important) properties  $P$  *do* transfer. We could give such proofs individually for different choices  $P$ , but this has a few drawbacks. First, proofs which at heart are very similar will be repeated. Second, proofs will be needed again for new or further property variants that we do not consider. Most important, however, from our perspective, ad hoc proofs fail to yield theoretical understanding; exactly what about a property allows it to transfer?

To address this we give a framework to obtain positive transference results. The intent is to formalize the above-described transference intuition. We start with a definition, of an object, denoted  $PS$ , that we call a *property specification*  $PS$ . While the game defining  $P$  would typically pick  $crs$  by running  $\Pi.C$ , the corresponding property specification sees the game output (result, win or not, of executing the game with an adversary) as a function of  $crs$ , effectively pulling the latter out of the game. We then give a general result (Theorem 5.2, the Transfer Theorem) saying that property specifications transfer successfully *as long as they are polynomial time*.

To apply this to show transference of a particular property  $P$ , we must specify the corresponding property specification  $PS$  and show that it is polynomial time. We do it for SND-E, zero-knowledge, witness indistinguishability and extractability to conclude that all these properties transfer successfully. (A property specification can be given for SND-P, but it is *not* polynomial time.)

DISCUSSION AND RELATED WORK. It is valuable, for applications, to have proof systems satisfying SND-P. The dual-system framework does not automatically provide this for its induced proof systems, because these properties do not transfer. This does not, however, say whether or not the induced proof systems have these properties for *particular* dual-mode systems in the literature. For example, does the PZK mode of the [GOS06b] system satisfy SND-P? We have found neither an attack to show it does not, nor a proof to show it does, and consider this an interesting question to settle.

Broadly, our work calls for care in using dual-mode systems in applications. One needs to check that the mode one is using has the desired properties, rather than expect that they arrive by transference. Our Transfer Theorem can help with such checks.

In our Theorem 4.4 counter-example showing that SND-P does not transfer, the relation  $R$  is CRS-dependent. To settle, by proof or counter-example, whether SND-P transfers for relations that are not CRS-dependent, is an interesting open question.

Abe and Fehr (AF) [AF07] show that if  $\Pi$  is statistical ZK for an **NP**-complete relation for  $R$  then it is unlikely that it can be proven SND-P via a certain restricted type of blackbox reduction to what they call a standard decision problem. Now suppose  $D\Pi$  is a dual-mode system for  $R$  such that  $D\Pi_1$  satisfies statistical ZK and  $D\Pi_0$  satisfies SND-P. Then the AF result says that, if mode indistinguishability is proven via a blackbox reduction to a standard decision problem, then one will be unlikely to be able to give a blackbox proof that SND-P transfers to  $D\Pi_1$ . This however does not rule out transference altogether; it rules out proving it in certain limited ways. (Possibly transference could be shown via non-black box reductions, or assumptions that are not standard decision problems.) In comparison, our Theorem 4.4 gives an example where transference not only cannot be proven, but demonstrably fails.

In Appendix D, we survey related work in detail, discussing different models, and different definitions of soundness, in the literature.

BUG FIX. Recall that one of our claims is that SND-E transfers. For the definition of SND-E given

in the preliminary version of our paper [AB20], this claim was not true. (In fact, for that definition, the counter-example in the proof of Theorem 4.4, showing SND-P does not transfer, also showed that SND-E does not transfer.) To recover the claim, we have, in this version, strengthened the definition of membership consciousness of an adversary, and thus the definition of SND-E. With this Theorem 5.3, showing SND-E transfers, is recovered.

## 2 Preliminaries

**NOTATION.** If  $\mathbf{w}$  is a vector then  $|\mathbf{w}|$  is its length (the number of its coordinates) and  $\mathbf{w}[i]$  is its  $i$ -th coordinate. Strings are identified with vectors over  $\{0, 1\}$ , so that  $|Z|$  denotes the length of a string  $Z$  and  $Z[i]$  denotes its  $i$ -th bit. By  $\varepsilon$  we denote the empty string or vector. By  $x||y$  we denote the concatenation of strings  $x, y$ . If  $x, y$  are equal-length strings then  $x \oplus y$  denotes their bitwise xor. If  $S$  is a finite set, then  $|S|$  denotes its size.

If  $X$  is a finite set, we let  $x \leftarrow_{\$} X$  denote picking an element of  $X$  uniformly at random and assigning it to  $x$ . Algorithms may be randomized unless otherwise indicated. If  $A$  is an algorithm, we let  $y \leftarrow A^{O_1, \dots}(x_1, \dots; \omega)$  denote running  $A$  on inputs  $x_1, \dots$  and coins  $\omega$ , with oracle access to  $O_1, \dots$ , and assigning the output to  $y$ . By  $y \leftarrow_{\$} A^{O_1, \dots}(x_1, \dots)$  we denote picking  $\omega$  at random and letting  $y \leftarrow A^{O_1, \dots}(x_1, \dots; \omega)$ . We let  $[A^{O_1, \dots}(x_1, \dots)]$  denote the set of all possible outputs of  $A$  when run on inputs  $x_1, \dots$  and with oracle access to  $O_1, \dots$ . An adversary is an algorithm. Running time is worst case, which for an algorithm with access to oracles means across all possible replies from the oracles. We use  $\perp$  (bot) as a special symbol to denote rejection, and it is assumed to not be in  $\{0, 1\}^*$ .

A function  $\nu: \mathbb{N} \rightarrow \mathbb{N}$  is *negligible* if for every positive polynomial  $p: \mathbb{N} \rightarrow \mathbb{R}$  there is a  $\lambda_p \in \mathbb{N}$  such that  $\nu(\lambda) \leq 1/p(\lambda)$  for all  $\lambda \geq \lambda_p$ . “PT” stands for “polynomial time.” By  $1^\lambda$  we denote the unary representation of the integer security parameter  $\lambda \in \mathbb{N}$ .

**GAMES.** We use the code-based game-playing framework of BR [BR06]. A game  $G$  (see Figure 2 for examples) starts with an optional INIT procedure, followed by a non-negative number of additional procedures, and ends with a FIN procedure. Execution of adversary  $A$  with game  $G$  consists of running  $A$  with oracle access to the game procedures (which accordingly are also called oracles), with the restrictions that  $A$ ’s first call must be to INIT (if present), its last call must be to FIN, and it can call these two procedures at most once each. The output of the execution is the output of FIN. By  $\Pr[G(A) \Rightarrow y]$  we denote the probability that the execution of game  $G$  with adversary  $A$  results in this output being  $y$ , and write just  $\Pr[G(A)]$  for the probability that the execution of game  $G$  with adversary  $A$  results in the output of the execution being the boolean true.

Note that our adversaries have no input or output. The role of what in other treatments is the adversary input is, for us, played by the response to the INIT query, and the role of what in other treatments is the adversary output is, for us, played by the query to FIN.

Different games may have procedures (oracles) with the same names. If we need to disambiguate, we may write  $G.O$  to refer to oracle  $O$  of game  $G$ .

In games, integer variables, set variables, boolean variables and string variables are assumed initialized, respectively, to 0, the empty set  $\emptyset$ , the boolean false and  $\perp$ .

**CDH AND DDH ASSUMPTIONS.** A group generator  $\mathbb{G}\mathbb{G}$  is a PT algorithm that takes as input a security parameter  $1^\lambda$  and outputs a triple  $(p, \mathbb{G}, g) \leftarrow_{\$} \mathbb{G}\mathbb{G}(1^\lambda)$  consisting of a prime  $p$ , (a description of) a group  $\mathbb{G}$  of order  $p$  and a generator  $g \in \mathbb{G} \setminus \{\mathbb{1}_{\mathbb{G}}\}$  of  $\mathbb{G}$ . We recall the Computational Diffie-Hellman (CDH) and Decisional Diffie-Hellman (DDH) problems associated to  $\mathbb{G}\mathbb{G}$  via the games in Figure 2. We define  $\mathbf{Adv}_{\mathbb{G}\mathbb{G}, \lambda}^{\text{cdh}}(A) = \Pr[\mathbf{G}_{\mathbb{G}\mathbb{G}, \lambda}^{\text{cdh}}(A)]$  to be the cdh-advantage of an adversary  $A$ . The CDH problem is hard for  $\mathbb{G}\mathbb{G}$ , or the CDH assumption holds for  $\mathbb{G}\mathbb{G}$ , if for every PT adversary  $A$

Game $\mathbf{G}_{\mathbb{G},\lambda}^{\text{cdh}}$	Game $\mathbf{G}_{\mathbb{G},\lambda}^{\text{ddh}}$
INIT(): 1 $(p, \mathbb{G}, g) \leftarrow_s \mathbf{GG}(1^\lambda)$ 2 $a, b \leftarrow_s \mathbb{Z}_p$ 3 Return $(p, \mathbb{G}, g, g^a, g^b)$ FIN( $C$ ): 4 Return $(C = g^{ab})$	INIT(): 1 $(p, \mathbb{G}, g) \leftarrow_s \mathbf{GG}(1^\lambda)$ ; $d \leftarrow_s \{0, 1\}$ ; $a, b, c \leftarrow_s \mathbb{Z}_p$ 2 If $(d = 1)$ then $C \leftarrow g^{ab}$ else $C \leftarrow g^c$ 3 Return $(p, \mathbb{G}, g, g^a, g^b, C)$ FIN( $d'$ ): 4 Return $(d' = d)$

Figure 2: Games defining the CDH and DDH assumptions for  $\mathbf{GG}$ .

the function  $\lambda \mapsto \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{cdh}}(\mathbf{A})$  is negligible. We define  $\mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(\mathbf{A}) = 2\Pr[\mathbf{G}_{\mathbf{GG},\lambda}^{\text{ddh}}(\mathbf{A})] - 1$  to be the ddh-advantage of an adversary  $\mathbf{A}$ . The DDH problem is hard for  $\mathbf{GG}$ , or the DDH assumption holds for  $\mathbf{GG}$ , if for every PT adversary  $\mathbf{A}$  the function  $\lambda \mapsto \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(\mathbf{A})$  is negligible.

### 3 Proof systems and Dual Mode proof systems

A proof system provides a way for one party (the prover) to prove some “claim” to another party (the verifier). A claim pertains to membership of an instance  $x$  in an **NP** language, the latter defined by an **NP** relation  $\mathbf{R}$ .

NP RELATIONS. Following [Gro06], and to cover existing proof systems, we allow the relation to depend on the CRS. Thus a relation is a function  $\mathbf{R}: \{0, 1\}^* \times \{0, 1\}^* \times \{0, 1\}^* \rightarrow \{\text{true}, \text{false}\}$  that takes the CRS  $\text{crs}$ , a instance  $x$  and a candidate witness  $w$  to return either **true** (saying  $w$  is a valid witness establishing the claim) or **false** (the witness fails to validate the claim). For  $\text{crs}, x \in \{0, 1\}^*$  we let  $\mathbf{R}(\text{crs}, x) = \{w : \mathbf{R}(\text{crs}, x, w) = \text{true}\}$  be the *witness set* of  $x$ .  $\mathbf{R}$  is said to be an **NP** relation if it is PT and there is a polynomial  $\mathbf{R.wl}: \mathbb{N} \rightarrow \mathbb{N}$  called the maximum witness length such that every  $w$  in  $\mathbf{R}(\text{crs}, x)$  has length at most  $\mathbf{R.wl}(|\text{crs}| + |x|)$  for all  $x \in \{0, 1\}^*$ . We let  $\mathbf{L}_{\mathbf{R}}(\text{crs}) = \{x : \mathbf{R}(\text{crs}, x) \neq \emptyset\}$  be the language associated to  $\mathbf{R}$  and  $\text{crs}$ .

PROOF SYSTEMS. A proof system is the name of the syntax for the primitive that enables the production and verification of such proofs, in the classical, single-mode sense. Soundness, zero-knowledge and many other things will be security properties for such (single-mode) proof systems. We give a general, unified syntax that allows us to recover, as special cases, various models such as the common reference/random string (CRS) models [BFM88, BDSMP91, Dam00, FF00, Ps05], the designated-verifier (DV) model [ES02, PsV06, DFN06], the designated-prover (DP) model [KW18, KNY19], and the preprocessing (PP) model [DMP90]. (Further discussion and history of these models is provided in Appendix D.) Now proceeding formally, a *proof system*  $\Pi$  specifies the following PT algorithms:

- *CRS generation.* Via  $(\text{crs}, \text{td}, k_{\mathbf{P}}, k_{\mathbf{V}}) \leftarrow_s \Pi.C(1^\lambda)$ , the crs-generation algorithm  $\Pi.C$  takes the (unary representation of the) security parameter and returns an output  $\text{crs}$  called the common reference string, a trapdoor  $\text{td}$ , a proving key  $k_{\mathbf{P}}$  and a verification key  $k_{\mathbf{V}}$ .
- *Proof generation.* Via  $\text{pf} \leftarrow_s \Pi.P(1^\lambda, \text{crs}, k_{\mathbf{P}}, x, w)$  the proof generation algorithm  $\Pi.P$  takes the unary security parameter,  $\text{crs}$ , a prover key  $k_{\mathbf{P}}$ , an instance  $x$  and a witness  $w$  to produce a proof string.
- *Proof verification.* Via  $d \leftarrow \Pi.V(1^\lambda, \text{crs}, k_{\mathbf{V}}, x, \text{pf})$  the deterministic proof verification algorithm  $\Pi.V$  produces a decision  $d \in \{\text{true}, \text{false}\}$  indicating whether or not it considers  $\text{pf}$  valid.

Figure 3: Left: Game defining mode indistinguishability for a dual-mode proof system  $\text{D}\Pi$ . Top Right: Games defining SND-P and SND-E soundness of proof system  $\Pi$  for relation  $\text{R}$ . Bottom Right: Game defining membership consciousness of the adversary playing it.

We say that  $\Pi$  satisfies completeness for relation  $\text{R}$  if  $\Pi.\text{V}(1^\lambda, \text{crs}, k_{\text{V}}, x, \text{pf}) = \text{true}$  for all  $\lambda \in \mathbb{N}$ , all  $(\text{crs}, \text{td}, k_{\text{P}}, k_{\text{V}}) \in [\Pi.\text{C}(1^\lambda)]$ , , all  $x \in \text{L}_{\text{R}}(\text{crs})$ , all  $w \in \text{R}(\text{crs}, x)$  and all  $\text{pf} \in [\Pi.\text{P}(1^\lambda, \text{crs}, k_{\text{P}}, x, w)]$ . This required completeness is perfect, but this can be relaxed if necessary.

RECOVERING THE DIFFERENT MODELS WITHIN OUR SYNTAX. The *common reference string model* (or *CRS model*) is the special case of our syntax in which  $\Pi.\text{C}$  always sets both the proving key and verification key to the empty string,  $k_{\text{P}} = k_{\text{V}} = \varepsilon$ . In some constructions [PsV06, ES02], the verification key is dependent on both the crs and the trapdoor  $\text{td}$ , while in other constructions [QRW19, LQR<sup>+</sup>19, LPWW20] it is dependent only on the crs. This distinction can be captured as a condition on  $\Pi.\text{C}$ . The *designated prover (DP) model* corresponds to  $\Pi.\text{C}$  always setting the verification key to the empty string,  $k_{\text{V}} = \varepsilon$ . The *preprocessing (PP) model* is captured by our syntax with no further restrictions. Here, the proving and verification keys may be dependent on the crs [KNYY19], or it might even be that the crs and  $\text{td}$  are set to the empty string and the keys do not depend on these parameters [KW18], all of which can be captured as conditions on  $\Pi.\text{C}$ .

DUAL-MODE SYSTEMS. We define a dual-mode proof system  $\text{D}\Pi$  as also specifying a PT CRS generation algorithm  $\text{D}\Pi.\text{C}$ , a PT proof generation algorithm  $\text{D}\Pi.\text{P}$  and a PT deterministic proof verification algorithm  $\text{D}\Pi.\text{V}$ . The syntax of the last two is identical to that in a proof system as defined above. The difference is the CRS generator  $\text{D}\Pi.\text{C}$ , which now (in addition to  $1^\lambda$ ) takes an input  $\mu \in \{0, 1\}$  called the *mode*, and returns a tuple  $(\text{crs}, \text{td}, k_{\text{P}}, k_{\text{V}})$ , as before.

For the common reference string model, the security requirement for a dual-mode proof system would be that the common reference strings created in the two modes are computationally indistinguishable. We suggest and introduce a generalization to our broader syntax, asking that the common reference strings and the proving and verification keys created in the two modes are indistinguishable. We call this mode indistinguishability. To formalize this, consider game  $\mathbf{G}_{\text{D}\Pi, \lambda}^{\text{mode}}$  of Figure 3 associated to dual-mode proof system  $\text{D}\Pi$ , and let the mode advantage of adversary  $A$  be defined by  $\mathbf{Adv}_{\text{D}\Pi, \lambda}^{\text{mode}}(A) = 2 \Pr[\mathbf{G}_{\text{D}\Pi, \lambda}^{\text{mode}}(A)] - 1$ . Mode indistinguishability asks that for all PT adversaries  $A$ , the function  $\lambda \mapsto \mathbf{Adv}_{\text{D}\Pi, \lambda}^{\text{mode}}(A)$  is negligible.

A dual-mode proof system  $\text{D}\Pi$  gives rise to two (standard) proof systems that we call *the proof systems induced by  $\text{D}\Pi$*  and denote  $\text{D}\Pi_1$  and  $\text{D}\Pi_0$ . Their proof generation and verification algorithms are those of  $\text{D}\Pi$ , meaning  $\text{D}\Pi_{\mu}.\text{P} = \text{D}\Pi.\text{P}$  and  $\text{D}\Pi_{\mu}.\text{V} = \text{D}\Pi.\text{V}$ , for both  $\mu \in \{0, 1\}$ . The difference between the two proof systems is in their CRS generation algorithms. Namely  $\text{D}\Pi_{\mu}.\text{C}$  is defined by:  $(\text{crs}, \text{td}, k_{\text{P}}, k_{\text{V}}) \leftarrow_{\$} \text{D}\Pi.\text{C}(1^{\lambda}, \mu)$ ; Return  $(\text{crs}, \text{td}, k_{\text{P}}, k_{\text{V}})$ .

COMPARISON WITH PRIOR NOTIONS. Unlike prior definitions [AFH<sup>+</sup>16, HU19, LPWW20], we do not tie to  $\text{D}\Pi$ , or mandate for it, any properties like soundness or ZK. These properties are defined (only) for (single-mode) proof systems. Accordingly, we can talk about whether or not the *induced* proof systems meet them. This allows us to decouple the core dual-mode concept from particular properties.

Our definition of mode indistinguishability asks that  $(\text{crs}, k_{\text{P}}, k_{\text{V}})$  be indistinguishable across the two modes, while prior definitions asked only that  $\text{crs}$  be indistinguishable across the modes. For the cases where dual-mode systems have been defined in the past, the two coincide. This is clearly true for the common reference string model, since here  $k_{\text{P}}, k_{\text{V}}$  are  $\varepsilon$ . For the designated-verifier setting of [LPWW20], our definition may at first seem different, but it isn't, because in [LPWW20],  $k_{\text{V}}$  is determined from  $\text{crs}$  by a key-generation algorithm, and doesn't depend on the trapdoor. (And meanwhile,  $k_{\text{P}} = \varepsilon$ .) A distinguisher can thus compute  $k_{\text{P}}, k_{\text{V}}$  from  $\text{crs}$ , making our definition equivalent to that of [LPWW20] in this case. The case where our definition is different from asking just for  $\text{crs}$  indistinguishability is when  $k_{\text{P}}, k_{\text{V}}$  depend on the coins underlying  $\text{crs}, \text{td}$ . Dual-mode systems for this setting, however, do not seem to have been defined prior to our work.

## 4 A study in soundness

We study soundness transference, showing that whether or not it holds depends on exactly how soundness is defined. We start thus with definitions.

SND-E AND SND-P SOUNDNESS. Soundness for a relation  $R$  asks that it be hard to create a valid proof for  $x \notin L_R(\text{crs})$ . We consider two ways to define this, namely the penalty style (SND-P) and the exclusion style (SND-E). These two styles, and their issues, were first formally considered in [BHK15] in the context of IND-CCA public-key encryption and KEMs. In the penalty style the adversary is penalized by the game when it submits a verification query where the claim is in the language, the game testing this and not allowing it to win in this case. In the exclusion style, the adversary is simply prohibited from making queries with claims in the language, meaning a claim of SND-E security quantifies only over the sub-class of adversaries that never make such queries (or make them with negligible probability).

Consider the games in Figure 3. A verification oracle  $\text{VF}$  is used to cover the designated-verifier setting. Game  $\mathbf{G}_{\Pi, R, \lambda}^{\text{snd-p}}$  includes the boxed code, so that when the adversary submits  $x \in L_R(\text{crs})$  to  $\text{VF}$ , the oracle returns the output of the verification algorithm on the query without setting the win flag. Otherwise, the game returns the decision taken by  $\Pi.\text{V}$  based on the instance  $x$

(now known not to be in  $L_R(\text{crs})$ ) and proof pf provided by the adversary, and only sets win if the verifier algorithm returns true in this case. From the transference perspective, the relevant fact is that the membership test will usually not be PT. We let  $\mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-p}}(A) = \Pr[\mathbf{G}_{\Pi,R,\lambda}^{\text{snd-p}}(A)]$  be the sndp-advantage of  $A$ . We say that  $\Pi$  is computational SND-P for  $R$  if for all PT  $A$  the function  $\lambda \mapsto \mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-p}}(A)$  is negligible; statistical SND-P if for all  $A$ , regardless of running time, the function  $\lambda \mapsto \mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-p}}(A)$  is negligible; perfect SND-P if for all  $A$ , regardless of running time,  $\mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-p}}(A) = 0$ . Saying just that  $\Pi$  is SND-P means it could be any of the three, meaning the default assumption is computational.

Game  $\mathbf{G}_{\Pi,R,\lambda}^{\text{snd-e}}$  excludes the boxed code. Regardless of whether or not  $x$  is in  $L_R(\text{crs})$ , the adversary wins if the verifier decision  $d$  computed at line 3 is true. This clearly doesn't by itself capture soundness, since the adversary can submit  $x \in L_R(\text{crs})$  to VF. This is ruled out, not in the game, but by restricting attention to adversaries that are what we call membership conscious. The benefit, from the transference perspective, is that the checks made by the game are now PT. We let  $\mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-e}}(A) = \Pr[\mathbf{G}_{\Pi,R,\lambda}^{\text{snd-e}}(A)]$  be the snde-advantage of  $A$ .

Consider game  $\mathbf{G}_{R,\lambda,C,V}^{\text{mcg}}$ , also in Figure 3. Here  $C, V$  are algorithms that parameterize the game, the second being deterministic and returning either true or false. They represent choices of CRS generation and verification algorithms of a proof system. We let  $\mathbf{Adv}_{R,\lambda,C,V}^{\text{mcg}}(A) = \Pr[\mathbf{G}_{R,\lambda,C,V}^{\text{mcg}}(A)]$ . We say that an adversary  $A$  is *membership conscious* for  $R$  if, for all choices of PT algorithms  $C, V$ , the function  $\lambda \mapsto \mathbf{Adv}_{R,\lambda,C,V}^{\text{mcg}}(A)$  is negligible. That is, the adversary almost never submits a VF query  $x$  that is in  $L_R(\text{crs})$ , regardless of how  $\text{crs}, k_P, k_V$  are distributed or chosen, and regardless of the replies given to its queries. We denote by  $\mathcal{A}_R^{\text{mc}}$  the class of all membership conscious adversaries for  $R$ . Now we say that  $\Pi$  is computational SND-E for  $R$  if for all PT  $A \in \mathcal{A}_R^{\text{mc}}$  the function  $\lambda \mapsto \mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-e}}(A)$  is negligible; statistical SND-E if for all  $A \in \mathcal{A}_R^{\text{mc}}$ , regardless of running time, the function  $\lambda \mapsto \mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-e}}(A)$  is negligible; perfect SND-E if for all  $A \in \mathcal{A}_R^{\text{mc}}$ , regardless of running time,  $\mathbf{Adv}_{\Pi,R,\lambda}^{\text{snd-e}}(A) = 0$ . Saying just that  $\Pi$  is SND-E means it could be any of the three, meaning the default assumption is computational.

In the preliminary version of this work [AB20], we had given a weaker definition of membership consciousness of  $A$ , that asked that  $A$  rarely query  $x \in L_R(\text{crs})$  only for the  $C, V$  being  $\Pi.C, \Pi.V$ , respectively. Under this definition, the claim that SND-E transfers was wrong. The reason was that whether or not  $A$  is membership conscious depended on  $\Pi$ , and was not maintained in moving from one mode to the other. We have now strengthened the definition of membership consciousness of  $A$ , asking that  $A$  rarely query  $x \in L_R(\text{crs})$  for *all* choices of  $C, V$ , not just those of  $\Pi$  made in game  $\mathbf{G}_{\Pi,R,\lambda}^{\text{snd-e}}$ . This makes membership consciousness independent of  $\Pi$ . Under this definition, we recover the result that SND-E transfers.

RELATIONS BETWEEN DEFINITIONS. To better understand the differences between the notions, we briefly study some relations between them. The following says that SND-P always implies SND-E:

**Proposition 4.1** *Let  $\Pi$  be a proof system and  $R$  a relation. If  $\Pi$  is computational (respectively statistical, perfect) SND-P then it is also computational (respectively statistical, perfect) SND-E.*

The proof is simple. Let  $A$  be a membership-conscious adversary for  $R$  that wins the SND-E game, violating SND-E. Then it also wins the SND-P game. (Its advantage as measured in the SND-P game can only be less than its advantage as measured in the SND-E game by a negligible amount.) And since SND-P quantifies over all PT adversaries (whether membership conscious for  $R$  or not), we have an adversary violating SND-P.

Another observation is that an unbounded adversary can check membership in the language. Due to this, the two formulations of soundness coincide in the statistical and perfect cases:

**Proposition 4.2** *Let  $\Pi$  be a proof system and  $R$  a relation. Then (1)  $\Pi$  is statistically SND-P for  $R$  iff it is statistically SND-E for  $R$ , and (2)  $\Pi$  is perfectly SND-P for  $R$  iff it is perfectly SND-E for  $R$ .*

The interesting case is the computational one. Here the two definitions do *not* coincide. We defer the proof of the following to Appendix A.

**Proposition 4.3** *Assume there exists a group generator relative to which DDH is hard. Then there exists a proof system  $\Pi$  and relation  $R$  such that (1)  $\Pi$  is SND-E for  $R$  but (2)  $\Pi$  is not SND-P for  $R$ .*

We will see in Section 6 that SND-P is what works for applications, SND-E being too weak. Thus, it is desirable that SND-P transfer. Unfortunately, we show below that, in general, it does not. Later, we will show that SND-E does, however, transfer.

NON-TRANSFERENCE OF SND-P. We give a counter-example to show that SND-P does not, in general, transfer. The counter-example constructs an explicit relation  $R$  and dual-mode proof system  $D\Pi$  such that  $D\Pi$  satisfies mode indistinguishability and SND-P holds in mode 1, but we can give an attack showing it does not hold in mode 0.  $D\Pi$  is a conventional (common reference string model) system, meaning  $k_P = k_V = \varepsilon$ , which means the result holds also in the designated verifier and prover settings.

**Theorem 4.4** *Assume there exists a group generator relative to which DDH is hard. Then there exists a dual-mode proof system  $D\Pi$  and relation  $R$  such that (1)  $D\Pi$  satisfies mode indistinguishability and (2)  $D\Pi_1$  satisfies SND-P for  $R$ , but (3)  $D\Pi_0$  does **not** satisfy SND-P for  $R$ .*

**Proof of Theorem 4.4:** Let  $GG$  be a group generator relative to which DDH is hard. Consider the relation  $R$  shown in Figure 4. Its first input is the CRS, which has the form  $(p, \mathbb{G}, g, A, B, C)$ , where  $(p, \mathbb{G}, g) \in [GG(1^\lambda)]$  and  $A, B, C \in \mathbb{G}$ . The second input  $X$  is the instance. The third input  $w$  is the witness, which we assume is in  $\mathbb{Z}_p$ . Recall that  $\text{dlog}_{\mathbb{G},g}(Y) \in \mathbb{Z}_p$  is the discrete logarithm of  $Y \in \mathbb{G}$  to base  $g$ . Let  $a, b, c \in \mathbb{Z}_p$  be such that  $A = g^a$ ,  $B = g^b$  and  $C = g^c$ . The relation tests three things, returning true iff all hold. The test that  $g^w = A$  forces the witness  $w$  to be  $a = \text{dlog}_{\mathbb{G},g}(A)$ , meaning it can have only one value. The third test requires  $X$  to be a group element, and the second test then says that  $X$  may be any group element *except*  $B^w = g^{bw} = g^{ba}$ . Recall that the language associated to  $R, (p, \mathbb{G}, g, A, B, C)$  is the set of all  $X$  for which there exists a witness  $w$  making  $R((p, \mathbb{G}, g, A, B, C), X, w) = \text{true}$ , so we have  $L_R((p, \mathbb{G}, g, A, B, C)) = \mathbb{G} \setminus \{g^{ab}\}$ , meaning it is all group elements except  $g^{ab}$ . Since violating soundness requires submitting an  $X \notin L_R((p, \mathbb{G}, g, A, B, C))$ , this means that there is only one choice of  $X$  that potentially violates soundness, namely  $g^{ab}$ .

Now consider the dual-mode proof system  $D\Pi$  whose algorithms  $D\Pi.C$ ,  $D\Pi.P$ ,  $D\Pi.V$  are described in Figure 4. The CRS generator picks a group  $\mathbb{G}$  and returns CRS  $(p, \mathbb{G}, g, A, B, C)$  such that, again letting  $A = g^a$ ,  $B = g^b$  and  $C = g^c$ , if  $\mu = 0$  then  $(A, B, C)$  is a DH-tuple—meaning  $C = g^{ab}$ —and if  $\mu = 1$  then  $A, B, C$  are uniform and independent group elements. Under the DDH assumption, the two CRSs are indistinguishable, while the proving and verification keys are identical in both modes since they are set to the empty string. Formally, this is claim (1) of the theorem statement, which we show by a reduction from the mode-indistinguishability of  $D\Pi$  to the DDH assumption for the group generator  $GG$ . For this, let  $A$  be a PT adversary. We construct the PT time adversary  $A_{\text{ddh}}$  shown in Figure 4. For all  $\lambda \in \mathbb{N}$  we have

$$\text{Adv}_{D\Pi,R,\lambda}^{\text{mode}}(A) \leq \text{Adv}_{GG,\lambda}^{\text{ddh}}(A_{\text{ddh}}),$$

Figure 4: Relation  $R$ , dual-mode proof system  $D\Pi$  and various adversaries for the proof of Theorem 4.4.

which justifies claim (1). The other algorithms of  $D\Pi$  perform trivially: The proof generator always returns the empty string as the proof, and the verifier algorithm always accepts.

Let  $D\Pi_0$  and  $D\Pi_1$  be the induced proof systems of  $D\Pi$ . We show claim (3) of the theorem by an attack, namely an adversary violating SND-P for  $D\Pi_0$ . The adversary  $A_0$  is shown in Figure 4. It starts, at line 1, by calling the INIT oracle of its game  $\mathbb{G}_{D\Pi_0, R, \lambda}^{\text{snd-p}}$ . The CRS  $(p, \mathbb{G}, g^a, g^b, C)$  in this game is generated by  $D\Pi_0.C$ , and hence  $C = g^{ab}$ . This gives the adversary an instance outside the language  $\mathcal{L}_R((p, \mathbb{G}, g^a, g^b, C))$ , namely  $X = C$ . It can now submit  $C$  to VF at line 3. What it submits as the proof does not matter (the choice made is the empty string) since  $D\Pi.V$  always accepts as long as the statement is in the group  $\mathbb{G}$ ; the challenge in violating SND-P was to find an instance outside the language. This VF query will set the win flag, and therefore this adversary will win the game when it calls FIN. We have  $\text{Adv}_{D\Pi_0, R, \lambda}^{\text{snd-p}}(A_0) = 1$ , establishing claim (3) of the theorem.

It remains to show claim (2), namely that  $D\Pi_1$  does satisfy SND-P. This is true under the CDH assumption on  $\mathbb{G}\mathbb{G}$ , which is implied by the DDH assumption we have made, and is proved by reduction. Given a PT adversary  $A$  trying to win game  $\mathbb{G}_{D\Pi_1, R, \lambda}^{\text{snd-p}}$ , we construct the PT cdh-adversary  $A_{\text{cdh}}$  shown in Figure 4. It is playing game  $\mathbb{G}_{\mathbb{G}\mathbb{G}, \lambda}^{\text{cdh}}$ . From the INIT oracle of that game, it obtains  $(p, \mathbb{G}, g, A, B)$ , and then runs  $A$ , simulating  $A$ 's INIT, VF, FIN oracles as shown. When  $A$  calls INIT, our  $A_{\text{cdh}}$  can return a legitimate mode-1 CRS by itself picking  $C$  at random and returning  $(p, \mathbb{G}, g, A, B, C)$ . When  $A$  calls VF with an argument  $X$  (and a proof  $\text{pf}$  which does not

matter) that, if it sets the win flag, will be  $g^{ab}$ , where  $A = g^a$  and  $B = g^b$ . If only one VF query was allowed,  $A_{\text{cdh}}$  could call its own FIN oracle with  $X$  to also win. However, since multiple VF queries can be made, the best  $A_{\text{cdh}}$  can do is to pick one of the statements queried to the VF by  $A$  at random to submit to its FIN oracle. This adds a multiplicative factor of the number of VF queries made by  $A$ , say  $q(\lambda)$ , to the bound. For all  $\lambda \in \mathbb{N}$  we have

$$\mathbf{Adv}_{\text{D}\Pi_0, \text{R}, \lambda}^{\text{snd-p}}(A) \leq q \cdot \mathbf{Adv}_{\text{GG}, \lambda}^{\text{cdh}}(A_{\text{cdh}}).$$

This completes the proof of claim (3) and thus of the Theorem.  $\blacksquare$

We will show later that SND-E does transfer. In light of this, a good sanity check is, where would the proof of Theorem 4.4 break down for SND-E?  $\text{D}\Pi_1$  would continue to satisfy SND-E. However, adversary  $A_0$  of Figure 4 does not violate the SND-E security of  $\text{D}\Pi_0$ . The reason is that it is not membership conscious for  $\text{R}$ . This reflects the strong formulation of the latter definition. While  $A_0$  does not make queries  $C \in \text{L}_{\text{R}}(\text{crs})$  when the CRS generation algorithm is  $\text{C} = \text{D}\Pi.\text{C}_0$ , there are other choices of  $\text{C}, \text{V}$  for which its query  $C$  would indeed be in  $\text{L}_{\text{R}}(\text{crs})$ , which violates the definition of membership consciousness for  $\text{R}$ .

In Theorem 4.4, the SND-P in mode-1 is computational, not statistical or perfect. A good question is, if mode-1 has statistical or perfect SND-P, then does it transfer, meaning does mode-0 have computational SND-P? The difficulty of proving the answer is “yes” remains, namely that the PT mode-indistinguishability adversary still has to test membership in the language, which may not be PT. We do not see a way in which stronger SND-P in mode-1 helps the transfer. But, for this case, neither do we have a counter-example.

In Theorem 4.4, the relation  $\text{R}$  depends on the CRS. An interesting open question is whether one can prove a similar negative result for a relation which does not depend on the CRS.

## 5 Transference framework and positive results

Let  $\text{D}\Pi$  be a dual-mode proof system satisfying mode indistinguishability. Recall we say that a “property”  $\text{P}$  (for example, zero-knowledge, soundness, extractability) transfers, if, for any  $\mu \in \{0, 1\}$ , we have: If  $\text{D}\Pi_\mu$  satisfies  $\text{P}$  then  $\text{D}\Pi_{1-\mu}$  satisfies the computational counterpart of  $\text{P}$ . In this Section we want to give positive results, showing some properties  $\text{P}$  do transfer.

We could try to do this exhaustively for target properties  $\text{P}_1, \text{P}_2, \dots$ : prove  $\text{P}_1$  transfers; then prove  $\text{P}_2$  transfers; and so on. This ad hoc approach has several drawbacks. First, proofs which at heart are very similar will be repeated. Second, proofs will be needed again for new or further properties that we do not consider. (Counting definitional variants in the literature, the number of properties of interest, namely the length of the list above, is rather large.) Third, we’d like a better theoretical understanding of what exactly are the attributes of a property that allow transference.

To address this, we give a framework to obtain positive transference results. We start by formalizing what we call a property specification  $\text{PS}$ . While the game defining  $\text{P}$  will pick the CRS and the proving and verification keys by running the CRS generator,  $\text{PS}$  will aim to see the adversary advantage in this game as a function of an external choice of CRS and keys, effectively pulling the choice of CRS and keys out of the game. We will then give a general result (the Transfer Theorem) saying that polynomial-time property specifications transfer successfully. To apply this to get a positive transfer result for some property  $\text{P}$  of interest, one then has to show that  $\text{P}$  can be captured by a polynomial time property specification  $\text{PS}$ . We will illustrate such applications by providing  $\text{PS}$  explicitly for a few choices of  $\text{P}$ . It will soon be easy to just look at the game defining  $\text{P}$  and see from it whether or not  $\text{P}$  can be cast as a polynomial-time  $\text{PS}$ , making it simple to see which properties transfer successfully.

$\text{PS}[\Pi].\text{Out}_{\text{crs},k_P,k_V,\lambda}(A)$ $st \leftarrow_s \text{PS.Stl}(1^\lambda, \text{crs}, k_P, k_V)$ $\text{Run } A^{\text{OR}}$ $\text{Return } out$	$\text{Oracle OR}(\text{Oname}, \text{Oarg}) \quad // \text{Oname} \in \text{PS.ONames}$ $(\text{Orsp}, st) \leftarrow_s \text{PS}[\Pi.P, \Pi.V].\text{Or}(\text{Oname}, \text{Oarg}, st)$ $\text{If } ((\text{Oname} = \text{Fin}) \text{ and } (out = \perp)) \text{ then}$ $out \leftarrow \text{Orsp}$ $\text{Return Orsp}$
---	---

Figure 5: Description of the execution of PS with a proof system  $\Pi$ , security parameter  $\lambda$ , input  $(\text{crs}, k_P, k_V) \in [\Pi.C(1^\lambda)]$  and an adversary  $A$ .

When the property specification PS is not polynomial time, our Transfer Theorem does not apply. This does not necessarily mean the property fails to transfer, but is an indication in that direction. To show that a particular (non polynomial-time) property P fails to transfer, one can give a counter-example, as with Theorem 4.4.

**PROPERTY SPECIFICATIONS.** A *property specification* PS is a function that, given a proof system  $\Pi$ , returns a triple  $(\text{PS.Stl}, \text{PS}[\Pi.P, \Pi.V].\text{Or}, \text{PS.type})$ . The first component PS.Stl is an algorithm that we refer to as the *state initializer*, and, as the notation indicates, it does not depend on  $\Pi$ . The second component  $\text{PS}[\Pi.P, \Pi.V].\text{Or}$  is an algorithm that we refer to as the *oracle responder*. We require that it invokes the prover and verifier algorithms of  $\Pi$  as oracles, so that if two proof systems have the same prover and verifier algorithms, the corresponding oracle responders are identical. The final component  $\text{PS.type} \in \{\text{dec}, \text{ser}\}$  is a keyword (formally, just a bit), indicating the type of problem, decision or search.

The state initializer takes the unary security parameter and a tuple  $(\text{crs}, k_P, k_V) \in [\Pi.C(1^\lambda)]$  to return an initial state,  $st \leftarrow_s \text{PS.Stl}(1^\lambda, \text{crs}, k_P, k_V)$ . Then, given a string  $\text{Oname} \in \text{PS.ONames} \subseteq \{0, 1\}^*$  called an *oracle name*, another string  $\text{Oarg}$  called an *oracle argument*, and also given a current state  $st$ , the oracle responder returns a pair  $(\text{Orsp}, st) \leftarrow_s \text{PS}[\Pi.P, \Pi.V].\text{Or}(\text{Oname}, \text{Oarg}, st)$  consisting of an *oracle response* Orsp and an updated state. The finite set of oracle names PS.ONames (also defined by PS but not allowed to depend on  $\Pi$ ) must contain the special name Fin, and it must be that the response Orsp is in the set  $\{\text{true}, \text{false}\}$  whenever  $(\text{Orsp}, st) \leftarrow_s \text{PS}[\Pi.P, \Pi.V].\text{Or}(\text{Fin}, \text{Oarg}, st)$ .

A property specification PS is said to be polynomial time (PT) if for every proof system  $\Pi$  there is a polynomial  $p$  such that algorithms PS.Stl and  $\text{PS}[\Pi.P, \Pi.V].\text{Or}$  run in time bounded by  $p$  applied to the lengths of their inputs.

We can run PS with a proof system  $\Pi$ , security parameter  $\lambda$ , input  $(\text{crs}, k_P, k_V) \in [\Pi.C(1^\lambda)]$  and an adversary  $A$  to get a boolean output, which is denoted  $\text{PS}[\Pi].\text{Out}_{\text{crs},\lambda}(A)$ . This output is determined by the process on the left in Figure 5, the right showing the oracle provided to  $A$ . In the figure, the execution initializes the state to  $st \leftarrow \text{PS.Stl}(1^\lambda, \text{crs}, k_P, k_V)$ . Then it runs  $A$  with access to the oracle OR shown on the right. Given the string naming an oracle, and an argument for it, OR provides the response as defined by  $\text{PS}[\Pi.P, \Pi.V].\text{Or}$ . The first time the oracle named Fin is called, the computed response is retained as  $out$ , and the latter becomes the output of the execution, namely the value returned as  $\text{PS}[\Pi].\text{Out}_{\text{crs},k_P,k_V,\lambda}(A)$ . We define the ps-advantage of  $A$ , depending on whether it is a search or decision problem, via

$$\text{Adv}_{\text{PS}[\Pi],\lambda}^{\text{ps}}(A) = \Pr \left[ \text{PS}[\Pi].\text{Out}_{\text{crs},k_P,k_V,\lambda}(A) : (\text{crs}, k_P, k_V) \leftarrow_s \Pi.C(1^\lambda) \right]$$

if  $\text{PS.type} = \text{ser}$ , and

$$\text{Adv}_{\text{PS}[\Pi],\lambda}^{\text{ps}}(A) = 2 \cdot \Pr \left[ \text{PS}[\Pi].\text{Out}_{\text{crs},k_P,k_V,\lambda}(A) : (\text{crs}, k_P, k_V) \leftarrow_s \Pi.C(1^\lambda) \right] - 1$$

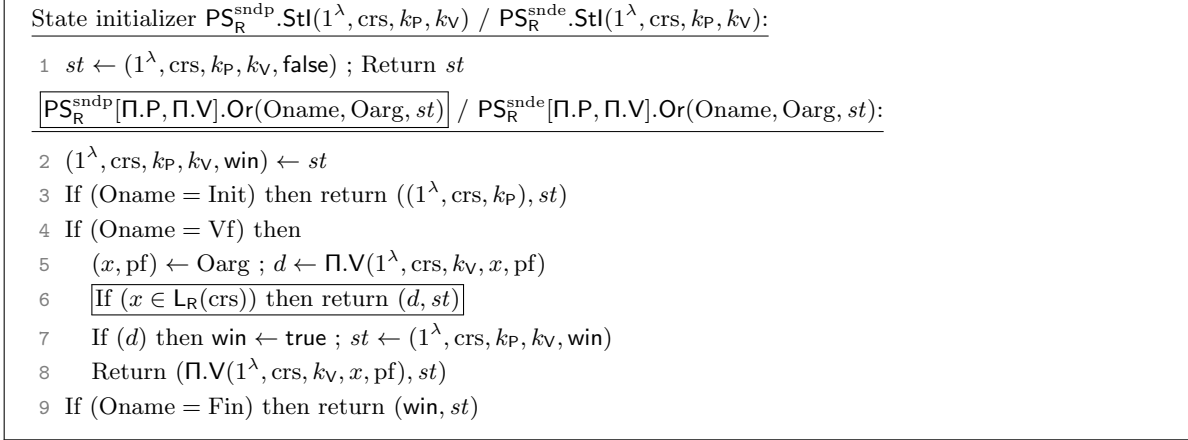

Figure 6: Algorithms associated by the SND-P property specification  $\text{PS}_R^{\text{sndp}}$  and the SND-E property specification  $\text{PS}_R^{\text{snde}}$  to proof system  $\Pi$ , where  $R$  is an NP-relation. The boxed code is only included in the SND-P specification.

if  $\text{PS.type} = \text{dec}$ . Here  $\Pr [\text{PS}[\Pi].\text{Out}_{\text{crs}, k_P, k_V, \lambda}(A) : (\text{crs}, k_P, k_V) \leftarrow_{\$} \Pi.C(1^\lambda)]$  is the probability that the output of the property specification is `true` when the CRS and proving and verification keys are chosen at random according to  $\Pi.C$ . We say that  $\Pi$  *satisfies PS for a class (set) of adversaries*  $\mathcal{A}_{\text{PS}}^{\text{ps}}$  if for every adversary  $A \in \mathcal{A}_{\text{PS}}^{\text{ps}}$ , the function  $\lambda \mapsto \text{Adv}_{\text{PS}[\Pi], \lambda}^{\text{ps}}(A)$  is negligible. Parameterizing the definition by a class of adversaries allows us to cover restrictions like membership-consciousness, and to capture computational and statistical variants of a property.

THE SND-E AND SND-P PROPERTY SPECIFICATIONS. We pause to illustrate property specifications by an example before providing the Transfer Theorem. We describe the property specifications  $\text{PS}_R^{\text{snde}}$  and  $\text{PS}_R^{\text{sndp}}$  corresponding to the SND-E and SND-P properties for  $R$ , respectively, in [Figure 6](#). The state initializer algorithms are the same for both, setting the initial state  $st$  to the `crs`, proving key and verification key they are given as input, together with the security parameter, and a boolean variable set to `false`. The oracle responder algorithms differ only at line 6, which is included for SND-P and excluded for SND-E. To each of the oracles `INIT`, `VF`, `FIN` in the games of [Figure 3](#), we associate a string naming it, these being `Init`, `Vf`, `Fin`, respectively, so that  $\text{PS}_R^{\text{snde}}.\text{ONames} = \text{PS}_R^{\text{sndp}}.\text{ONames} = \{\text{Init}, \text{Vf}, \text{Fin}\}$ . Passing the name of an oracle, and arguments for it, to the oracle responder, results in the response of that oracle being returned. (Also returned is the state, which is updated here, but may not be in other property specifications.) The problem type is  $\text{PS}_R^{\text{snde}}.\text{type} = \text{PS}_R^{\text{sndp}}.\text{type} = \text{ser}$ , meaning both are search problems. As this shows, there is a quite direct connection between the games and the property specification, the key difference being that the latter has the CRS as input while the former picks it internally.

We connect the actual properties with their formal property specifications via the following, which says that, for  $x \in \{\text{e}, \text{p}\}$ , the `sndx-advantage` is identical to the corresponding `ps-advantage`.

**Proposition 5.1** *Let  $R$  be an NP-relation,  $\Pi$  a proof system and  $A$  an adversary. Then for all  $\lambda \in \mathbb{N}$  we have:*

$$\text{Adv}_{\Pi, R, \lambda}^{\text{snd-e}}(A) = \text{Adv}_{\text{PS}_R^{\text{snde}}[\Pi], \lambda}^{\text{ps}}(A) \quad \text{and} \quad \text{Adv}_{\Pi, R, \lambda}^{\text{snd-p}}(A) = \text{Adv}_{\text{PS}_R^{\text{sndp}}[\Pi], \lambda}^{\text{ps}}(A).$$

In the case of SND-E, [Proposition 5.1](#) does not restrict to membership conscious adversaries, even though these are the ones of eventual interest; the claim of the Proposition is true for all adversaries.

The key difference between the two property specifications is in their running time. Property specification  $\text{PS}_R^{\text{snde}}$  is polynomial time. But property specification  $\text{PS}_R^{\text{sndp}}$  is only polynomial time if testing membership of  $x$  in  $L_R(\text{crs})$  can be done in time polynomial in the lengths of  $x$  and  $\text{crs}$ , which, for relations of interest, is usually *not* the case. Our Transfer Theorem applies to  $\text{PS}_R^{\text{snde}}$  but, due to its not in general being polynomial time, not to  $\text{PS}_R^{\text{sndp}}$ .

**TRANSFER THEOREM.** We are now ready to state the Transfer Theorem. Refer above for what it means for a proof system  $\Pi$  to satisfy a property specification  $\text{PS}$  for a class of adversaries  $\mathcal{A}_{\text{PS}}^{\text{ps}}$ . The following says that when this is true in one mode of a dual-mode proof system  $\text{D}\Pi$ , then its computational counterpart is true in the other mode. Below, we let  $\mathcal{A}^{\text{PT}}$  be the class of all polynomial-time adversaries; the intersection of  $\mathcal{A}_{\text{PS}}^{\text{ps}}$  with  $\mathcal{A}^{\text{PT}}$  in the conclusion of the Theorem captures that the transferred property is the computational counterpart of the original one. The proof is in Appendix B.

**Theorem 5.2** *Let  $\text{D}\Pi$  be a dual-mode proof system that is mode indistinguishable. Let  $\mu \in \{0, 1\}$ . Let  $\text{PS}$  be a polynomial-time property specification. Assume  $\text{D}\Pi_\mu$  satisfies  $\text{PS}$  for a class of adversaries  $\mathcal{A}_{\text{PS}}^{\text{ps}}$ . Then  $\text{D}\Pi_{1-\mu}$  satisfies  $\text{PS}$  for the class of adversaries  $\mathcal{A}_{\text{PS}}^{\text{ps}} \cap \mathcal{A}^{\text{PT}}$ .*

**TRANSFERENCE OF SND-E.** We can apply this to conclude transference of SND-E as follows.

**Theorem 5.3** *Let  $R$  be an NP relation. Let  $\text{D}\Pi$  be a dual-mode proof system for relation  $R$  that is mode-indistinguishable, and let  $\mu \in \{0, 1\}$ . Assume  $\text{D}\Pi_\mu$  is SND-E for  $R$ . Then  $\text{D}\Pi_{1-\mu}$  is SND-E for  $R$ .*

**Proof of Theorem 5.3:** From Proposition 5.1, we know that  $\text{Adv}_{\text{D}\Pi_\mu, R, \lambda}^{\text{snd-e}}(A) = \text{Adv}_{\text{PS}_R^{\text{snde}}[\text{D}\Pi_\mu], \lambda}^{\text{ps}}(A)$  and  $\text{Adv}_{\text{D}\Pi_{1-\mu}, R, \lambda}^{\text{snd-e}}(A) = \text{Adv}_{\text{PS}_R^{\text{snde}}[\text{D}\Pi_{1-\mu}], \lambda}^{\text{ps}}(A)$ , where the SND-E property specification is as described in Figure 6. We also know from the definition of the SND-E property specification that it is a polynomial-time property specification. As a result, we can use the result of Theorem 5.2. More specifically, we can apply Equation (1) from the proof of Theorem 5.2 to this setting:

$$\text{Adv}_{\text{PS}_R^{\text{snde}}[\text{D}\Pi_{1-\mu}], \lambda}^{\text{ps}}(A) \leq \text{Adv}_{\text{PS}_R^{\text{snde}}[\text{D}\Pi_\mu], \lambda}^{\text{ps}}(A) + 2 \cdot \text{Adv}_{\text{D}\Pi, \lambda}^{\text{mode}}(A_\mu).$$

In the above equation, the adversary  $A \in \mathcal{A}_R^{\text{mc}}$  is membership conscious for the relation  $R$ . We can now use the mode indistinguishability property of  $\text{D}\Pi$  and the assumption that  $\text{D}\Pi_\mu$  is SND-E for  $R$  to conclude that  $\text{D}\Pi_{1-\mu}$  is SND-E for  $R$ . ■

The above proof makes use of the updated (stronger) definition of membership consciousness, which ensures that the adversary  $A$  is membership-conscious across both modes of  $\text{D}\Pi$ .

This is however a simple case. For ZK, the property specification definition is more delicate, and some work will be needed to check that it obeys the conditions required by the definition of a property specification.

We now turn to establishing transference for other properties. We will give their definitions, and the property specifications, side by side.

**ZERO KNOWLEDGE.** The property specification allowing showing transference for ZK is more interesting, in part because it is a decision problem.

We formalize what is usually called adaptive zero knowledge, as the form most useful for applications. A *simulator*  $S$  specifies a PT algorithm  $S.C$  (the simulation CRS-generator) and a PT algorithm  $S.P$  (the simulation proof-generator). Consider game  $\mathbf{G}_{\Pi, R, S, \lambda}^{\text{zk}}$  specified in Figure 7. ZK-adversary  $A$  can adaptively request proofs by supplying an instance and a valid witness for it. The

<p><b>Game <math>\mathbf{G}_{\Pi, R, S, \lambda}^{\text{zk}}</math></b></p> <p><b>INIT():</b></p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}_1, \text{td}_1, k_P, k_{V1}) \leftarrow \Pi.C(1^\lambda)</math></li> <li>2 <math>(\text{crs}_0, \text{td}_0, k_{V0}) \leftarrow \mathbf{S}.C(1^\lambda)</math></li> <li>3 <math>b \leftarrow \{0, 1\}</math>; <math>\text{crs} \leftarrow \text{crs}_b</math>; <math>k_V \leftarrow k_{Vb}</math></li> <li>4 Return <math>(1^\lambda, \text{crs}, k_V)</math></li> </ol> <p><b>PF(<math>x, w</math>):</b></p> <ol style="list-style-type: none"> <li>5 If <math>(\neg R(\text{crs}, x, w))</math> then return <math>\perp</math></li> <li>6 If <math>(b = 1)</math> then</li> <li>7   <math>\text{pf} \leftarrow \Pi.P(1^\lambda, \text{crs}, k_P, x, w)</math></li> <li>8 Else <math>\text{pf} \leftarrow \mathbf{S}.P(1^\lambda, \text{crs}, k_V, \text{td}_0, x)</math></li> <li>9 Return <math>\text{pf}</math></li> </ol> <p><b>FIN(<math>b'</math>):</b></p> <ol style="list-style-type: none"> <li>10 Return <math>(b' = b)</math></li> </ol>	<p><b>State initializer <math>\mathbf{PS}_{R, S}^{\text{zk}}.\text{Stl}(1^\lambda, \text{crs}, k_P, k_V)</math>:</b></p> <ol style="list-style-type: none"> <li>1 <math>b \leftarrow \{0, 1\}</math></li> <li>2 If <math>(b = 0)</math> then <math>(\text{crs}, \text{td}, k_V) \leftarrow \mathbf{S}.C(1^\lambda)</math></li> <li>3 <math>st \leftarrow (1^\lambda, \text{crs}, \text{td}, k_P, k_V, b)</math>; Return <math>st</math></li> </ol> <p><b><math>\mathbf{PS}_{R, S}^{\text{zk}}[\Pi.P, \Pi.V].\text{Or}(\text{Oname}, \text{Oarg}, st)</math>:</b></p> <ol style="list-style-type: none"> <li>4 <math>(1^\lambda, \text{crs}, \text{td}, k_P, k_V, b) \leftarrow st</math></li> <li>5 If <math>(\text{Oname} = \text{Init})</math> then</li> <li>6   return <math>(\text{crs}, k_V, st)</math></li> <li>7 If <math>(\text{Oname} = \text{Pf})</math> then</li> <li>8   <math>(x, w) \leftarrow \text{Oarg}</math></li> <li>9   If <math>(\neg R(\text{crs}, x, w))</math> then</li> <li>10    return <math>(\perp, st)</math></li> <li>11   If <math>(b = 1)</math> then</li> <li>12     <math>\text{pf} \leftarrow \Pi.P(1^\lambda, \text{crs}, k_P, x, w)</math></li> <li>13    Else <math>\text{pf} \leftarrow \mathbf{S}.P(1^\lambda, \text{crs}, k_V, \text{td}, x)</math></li> <li>14    Return <math>(\text{pf}, st)</math></li> <li>15 If <math>(\text{Oname} = \text{Fin})</math> then</li> <li>16   <math>b' \leftarrow \text{Oarg}</math>; Return <math>((b = b'), st)</math></li> </ol>
---	---

Figure 7: Left: Game defining zero-knowledge (relative to simulator  $\mathbf{S}$ ) for proof system  $\Pi$ . Right: The state initializer and oracle responder algorithms associated by the ZK property specification  $\mathbf{PS}_{R, S}^{\text{zk}}$  to proof system  $\Pi$ , where  $R$  is an NP-relation and  $\mathbf{S}$  is a simulator.

proof is produced either by the honest prover using the witness, or by the proof simulator  $\mathbf{S}.P$  using a simulation trapdoor  $\text{td}_0$ . The adversary outputs a guess  $b'$  as to whether the proofs were real or simulated. Let  $\mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(A) = 2 \Pr[\mathbf{G}_{\Pi, R, S, \lambda}^{\text{zk}}(A)] - 1$  be its zk-advantage relative to  $\mathbf{S}$ .

We say that  $\Pi$  is computational ZK for  $R$  if there exists a simulator  $\mathbf{S}$  such that for all PT  $A$  the function  $\lambda \mapsto \mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(A)$  is negligible; statistical ZK for  $R$  if there exists a simulator  $\mathbf{S}$  such that for all  $A$ , regardless of running time, the function  $\lambda \mapsto \mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(A)$  is negligible; and perfect ZK for  $R$  if there exists a simulator  $\mathbf{S}$  such that for all  $A$ , regardless of running time,  $\mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(A) = 0$ . Saying just that  $\Pi$  is ZK means it could be any of the three, meaning the default assumption is computational.

We describe the property specification  $\mathbf{PS}_{R, S}^{\text{zk}}$  corresponding to the ZK property for relation  $R$  and simulator  $\mathbf{S}$ . Figure 7 shows the algorithms that it associates to a given proof system  $\Pi$ . While game  $\mathbf{G}_{\Pi, R, S}^{\text{zk}}$  of Figure 7 picks the CRS and the proving and verification keys via  $\Pi.C$  when  $b = 1$ , state initializer  $\mathbf{PS}_{R, S}^{\text{zk}}.\text{Stl}$  takes the CRS and the proving and verification keys as input and sets this CRS as the CRS when  $b = 1$ . If  $b = 0$ , this CRS is overwritten at line 2. The state is the 6-tuple at line 4. To each oracle  $\text{INIT}, \text{PF}, \text{FIN}$  in game  $\mathbf{G}_{\Pi, R, S}^{\text{zk}}$  we associate a string naming it, these being  $\text{Init}, \text{Pf}, \text{Fin}$ , respectively, so that  $\mathbf{PS}_{R, S}^{\text{zk}}.\text{ONames} = \{\text{Init}, \text{Pf}, \text{Fin}\}$ . Passing the name of an oracle, and arguments for it, to  $\mathbf{PS}_{R, S}^{\text{zk}}[\Pi.P, \Pi.V].\text{Or}$ , results in the response of that oracle being returned. (Also returned is the state, which here is not updated, but may be in other property specifications.) The type is  $\mathbf{PS}_{R, S}^{\text{zk}}.\text{type} = \text{dec}$ , meaning this is a decision problem.

To connect the ZK property with the property specification  $\mathbf{PS}_{R, S}^{\text{zk}}$ , we see that the zk-advantage is identical to the ps-advantage:

**Proposition 5.4** *Let  $R$  be an NP-relation,  $\mathbf{S}$  a simulator,  $\Pi$  a proof system and  $A$  an adversary.*

<p><b>Game <math>\mathbf{G}_{\Pi, R, \lambda}^{\text{wi}}</math></b></p> <p><b>INIT():</b></p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}, \text{td}, k_P, k_V) \leftarrow \text{P.C}(1^\lambda)</math></li> <li>2 <math>b \leftarrow \text{s } \{0, 1\}</math></li> <li>3 Return <math>(1^\lambda, \text{crs}, k_V)</math></li> </ol> <p><b>PF(<math>x, w_0, w_1</math>):</b></p> <ol style="list-style-type: none"> <li>4 <math>d_0 \leftarrow \text{R}(\text{crs}, x, w_0)</math></li> <li>5 <math>d_1 \leftarrow \text{R}(\text{crs}, x, w_1)</math></li> <li>6 If <math>(\neg d_0</math> or <math>\neg d_1)</math> then return <math>\perp</math></li> <li>7 <math>\text{pf} \leftarrow \text{P}(\text{crs}, k_P, x, w_b)</math></li> <li>8 Return pf</li> </ol> <p><b>FIN(<math>b'</math>):</b></p> <ol style="list-style-type: none"> <li>9 Return <math>(b' = b)</math></li> </ol>	<p><b>State initializer <math>\text{PS}_R^{\text{wi}}.\text{Stl}(1^\lambda, \text{crs}, k_P, k_V)</math>:</b></p> <ol style="list-style-type: none"> <li>1 <math>b \leftarrow \text{s } \{0, 1\}</math> ; <math>st \leftarrow (1^\lambda, \text{crs}, k_P, k_V, b)</math></li> <li>2 Return <math>st</math></li> </ol> <p><b><math>\text{PS}_R^{\text{wi}}[\Pi.P, \Pi.V].\text{Or}(\text{Oname}, \text{Oarg}, st)</math>:</b></p> <ol style="list-style-type: none"> <li>3 <math>(1^\lambda, \text{crs}, k_P, k_V, b) \leftarrow st</math></li> <li>4 If <math>(\text{Oname} = \text{Init})</math> then return <math>(\text{crs}, k_V, st)</math></li> <li>5 If <math>(\text{Oname} = \text{Pf})</math> then</li> <li>6 <math>(x, w_0, w_1) \leftarrow \text{Oarg}</math></li> <li>7 If <math>(\neg \text{R}(\text{crs}, x, w_0)</math> or <math>\neg \text{R}(\text{crs}, x, w_1))</math> then</li> <li>8 Return <math>(\perp, st)</math></li> <li>9 <math>\text{pf} \leftarrow \text{P}(\text{crs}, k_P, x, w_b)</math></li> <li>10 Return <math>(\text{pf}, st)</math></li> <li>11 If <math>(\text{Oname} = \text{Fin})</math> then</li> <li>12 <math>b' \leftarrow \text{Oarg}</math> ; Return <math>((b = b'), st)</math></li> </ol>
--	---

Figure 8: Left: Games defining witness indistinguishability of proof system  $\Pi$ . Right: The state initializer and oracle responder algorithms associated by the WI property specification  $\text{PS}_R^{\text{wi}}$  to proof system  $\Pi$ , where  $R$  is an NP-relation.

Then for all  $\lambda \in \mathbb{N}$  we have:

$$\text{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(\mathbb{A}) = \text{Adv}_{\text{PS}_{R, S}^{\text{zk}}[\Pi], \lambda}^{\text{ps}}(\mathbb{A}).$$

TRANSFERENCE OF ZK. We can now conclude the transference of ZK as follows.

**Theorem 5.5** *Let  $R$  be an NP relation. Let  $D\Pi$  be a dual-mode proof system for relation  $R$  that is mode-indistinguishable, and let  $\mu \in \{0, 1\}$ . Assume  $D\Pi_\mu$  is ZK for  $R$ . Then  $D\Pi_{1-\mu}$  is ZK for  $R$ .*

**Proof of Theorem 5.5:** From the assumption that  $D\Pi_\mu$  is ZK for  $R$ , we know that there exists a simulator  $S$  relative to which the function  $\lambda \mapsto \text{Adv}_{D\Pi_\mu, R, S, \lambda}^{\text{zk}}(\mathbb{A})$  is negligible. From Proposition 5.4, we know that  $\text{Adv}_{D\Pi_\mu, R, S, \lambda}^{\text{zk}}(\mathbb{A}) = \text{Adv}_{\text{PS}_{R, S}^{\text{zk}}[D\Pi_\mu], \lambda}^{\text{ps}}(\mathbb{A})$  and  $\text{Adv}_{D\Pi_{1-\mu}, R, S, \lambda}^{\text{zk}}(\mathbb{A}) = \text{Adv}_{\text{PS}_{R, S}^{\text{zk}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(\mathbb{A})$ , where the ZK property specification is as described in Figure 7. We also know from the definition of the ZK property specification that it is a polynomial-time property specification. As a result, we can use the result of Theorem 5.2, that is, we can apply Equation (1) from the proof of Theorem 5.2 to this setting:

$$\text{Adv}_{\text{PS}_{R, S}^{\text{zk}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(\mathbb{A}) \leq \text{Adv}_{\text{PS}_{R, S}^{\text{zk}}[D\Pi_\mu], \lambda}^{\text{ps}}(\mathbb{A}) + 2 \cdot \text{Adv}_{D\Pi, \lambda}^{\text{mode}}(\mathbb{A}_\mu).$$

We can now use the mode indistinguishability property of  $D\Pi$  and the assumption that  $D\Pi_\mu$  is ZK for  $R$  to conclude that  $D\Pi_{1-\mu}$  is ZK for  $R$  (the same simulator  $S$  works for both modes).  $\blacksquare$

WITNESS INDISTINGUISHABILITY. This asks that, knowing  $x \in \text{L}_R(\text{crs})$  and knowing two witnesses  $w_0, w_1 \in \text{R}(\text{crs}, x)$ , it is hard to tell under which of the two a proof has been computed [FS90]. Consider game  $\mathbf{G}_{\Pi, R, \lambda}^{\text{wi}}$  specified in Figure 8. Let  $\text{Adv}_{\Pi, R, \lambda}^{\text{wi}}(\mathbb{A}) = 2 \Pr[\mathbf{G}_{\Pi, R, \lambda}^{\text{wi}}(\mathbb{A})] - 1$ . We say that  $\Pi$  is computational WI for  $R$  if for all PT  $\mathbb{A}$  the function  $\lambda \mapsto \text{Adv}_{\Pi, R, \lambda}^{\text{wi}}(\mathbb{A})$  is negligible; statistical WI if for all  $\mathbb{A}$ , regardless of running time, the function  $\lambda \mapsto \text{Adv}_{\Pi, R, \lambda}^{\text{wi}}(\mathbb{A})$  is negligible; perfect WI

if for all  $A$ , regardless of running time,  $\lambda \mapsto \mathbf{Adv}_{\Pi, R, \lambda}^{\text{wi}}(A) = 0$ . Saying just that  $\Pi$  is WI means it could be any of the three, meaning the default assumption is computational.

We describe the algorithms of the property specification  $\text{PS}_{\mathbb{R}}^{\text{wi}}$  corresponding to the WI property for the relation  $R$  in Figure 8. The type is  $\text{PS}_{\mathbb{R}}^{\text{wi}}.\text{type} = \text{dec}$ , meaning it is a decision problem. Connecting the WI property with its property specification  $\text{PS}_{\mathbb{R}}^{\text{wi}}$ , we claim that the wi-advantage is identical to the ps-advantage.

**Proposition 5.6** *Let  $R$  be an NP-relation,  $\Pi$  a proof system and  $A$  an adversary. Then for all  $\lambda \in \mathbb{N}$  we have:*

$$\mathbf{Adv}_{\Pi, R, \lambda}^{\text{wi}}(A) = \mathbf{Adv}_{\text{PS}_{\mathbb{R}}^{\text{wi}}[\Pi], \lambda}^{\text{ps}}(A) .$$

TRANSFERENCE OF WI. We can now conclude the transference of WI as follows.

**Theorem 5.7** *Let  $R$  be an NP relation. Let  $D\Pi$  be a dual-mode proof system for relation  $R$  that is mode-indistinguishable, and let  $\mu \in \{0, 1\}$ . Assume  $D\Pi_{\mu}$  is WI for  $R$ . Then  $D\Pi_{1-\mu}$  is WI for  $R$ .*

**Proof of Theorem 5.7:** From Proposition 5.6, we know that  $\mathbf{Adv}_{D\Pi_{\mu}, R, \lambda}^{\text{wi}}(A) = \mathbf{Adv}_{\text{PS}_{\mathbb{R}}^{\text{wi}}[D\Pi_{\mu}], \lambda}^{\text{ps}}(A)$  and  $\mathbf{Adv}_{D\Pi_{1-\mu}, R, \lambda}^{\text{wi}}(A) = \mathbf{Adv}_{\text{PS}_{\mathbb{R}}^{\text{wi}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(A)$ , where the WI property specification is as described in Figure 8. We also know from the definition of the WI property specification that it is a polynomial-time property specification. As a result, we can use the result of Theorem 5.2, that is, we can apply Equation (1) from the proof of Theorem 5.2 to this setting:

$$\mathbf{Adv}_{\text{PS}_{\mathbb{R}}^{\text{wi}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(A) \leq \mathbf{Adv}_{\text{PS}_{\mathbb{R}}^{\text{wi}}[D\Pi_{\mu}], \lambda}^{\text{ps}}(A) + 2 \cdot \mathbf{Adv}_{D\Pi, \lambda}^{\text{mode}}(A_{\mu}) .$$

We can now use the mode indistinguishability property of  $D\Pi$  and the assumption that  $D\Pi_{\mu}$  is WI for  $R$  to conclude that  $D\Pi_{1-\mu}$  is WI for  $R$ .  $\blacksquare$

XT EXTRACTABILITY. The notion of  $\Pi$  being a proof of knowledge [GMR89, BG93, DP92] for  $R$  requires that whenever a (potentially cheating) prover, modeled as the adversary, is able to produce a valid proof, there is an extractor that, based on a trapdoor underlying the common reference string, can extract the witness from the information available to the adversary. We generalize extractability for the different models we consider along the lines of [CC18] (which defined knowledge-extractability for DV-NIZKs). Our formalization is via game  $\mathbf{G}^{\text{xt}}$  specified in Figure 3. It is parameterized by an *extractor*  $S$ , an object that specifies algorithms  $S.C$  (the extraction-CRS generator) and  $S.X$  (the extraction witness-generator). Let  $\mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{xt}}(A) = \Pr[\mathbf{G}_{\Pi, R, S, \lambda}^{\text{xt}}(A)]$  be the xt-advantage of  $A$ .

The notion of  $\Pi$  being XT-secure would be that there exists a polynomial time extractor  $S$  such that  $\lambda \mapsto \mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{xt}}(A)$  is negligible for all polynomial time adversaries  $A$ .

THE XT PROPERTY SPECIFICATION. We describe the property specification  $\text{PS}_{\mathbb{R}, S}^{\text{xt}}$  corresponding to the XT property for the relation  $R$  in Figure 9. The type is  $\text{PS}_{\mathbb{R}, S}^{\text{xt}}.\text{type} = \text{ser}$ , meaning it is a search problem. Connecting the XT property with its property specification  $\text{PS}_{\mathbb{R}, S}^{\text{xt}}$ , we claim that the xt-advantage is identical to the ps-advantage.

**Proposition 5.8** *Let  $R$  be an NP-relation,  $\Pi$  a proof system and  $A$  an adversary. Then for all  $\lambda \in \mathbb{N}$  we have:*

$$\mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{xt}}(A) = \mathbf{Adv}_{\text{PS}_{\mathbb{R}, S}^{\text{xt}}[\Pi], \lambda}^{\text{ps}}(A) .$$

<p><b>Game <math>\mathbf{G}_{\Pi, R, S, \lambda}^{\text{xt}}</math></b></p> <p><b>INIT():</b></p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}, \text{td}, k_P, k_V) \leftarrow \text{S.C}(1^\lambda)</math></li> <li>2 Return <math>(1^\lambda, \text{crs}, k_P)</math></li> </ol> <p><b>VF(<math>x, \text{pf}</math>):</b></p> <ol style="list-style-type: none"> <li>3 Return <math>\Pi.V(1^\lambda, \text{crs}, k_V, x, \text{pf})</math></li> </ol> <p><b>FIN(<math>x, \text{pf}</math>):</b></p> <ol style="list-style-type: none"> <li>4 If <math>(\neg \Pi.V(1^\lambda, \text{crs}, k_V, x, \text{pf}))</math> then</li> <li>5     return false</li> <li>6 <math>w \leftarrow \text{S.X}(1^\lambda, \text{crs}, \text{td}, x, \text{pf})</math></li> <li>7 Return <math>\neg R(\text{crs}, x, w)</math></li> </ol>	<p><b>State initializer <math>\text{PS}_{R, S}^{\text{xt}}.\text{Stl}(1^\lambda, \text{crs}, k_P, k_V)</math>:</b></p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}', \text{td}, k'_P, k'_V) \leftarrow \text{S.C}(1^\lambda)</math></li> <li>2 <math>st \leftarrow (1^\lambda, \text{crs}', \text{td}, k'_P, k'_V)</math>; Return <math>st</math></li> </ol> <p><b><math>\text{PS}_{R, S}^{\text{xt}}[\Pi.P, \Pi.V].\text{Or}(\text{Oname}, \text{Oarg}, st)</math>:</b></p> <ol style="list-style-type: none"> <li>3 <math>(1^\lambda, \text{crs}, \text{td}, k_P, k_V) \leftarrow st</math></li> <li>4 If <math>(\text{Oname} = \text{Init})</math> then</li> <li>5     Return <math>((1^\lambda, \text{crs}, k_P), st)</math></li> <li>6 If <math>(\text{Oname} = \text{Vf})</math> then</li> <li>7     Return <math>\Pi.V(1^\lambda, \text{crs}, k_V, x, \text{pf})</math></li> <li>8 If <math>(\text{Oname} = \text{Fin})</math> then</li> <li>9     <math>(x, \text{pf}) \leftarrow \text{Oarg}</math></li> <li>10    If <math>(\Pi.V(1^\lambda, \text{crs}, k_V, x, \text{pf}) = \text{false})</math> then</li> <li>11     Return false</li> <li>12    <math>w \leftarrow \text{S.X}(1^\lambda, \text{crs}, \text{td}, x, \text{pf})</math></li> <li>13    Return <math>((R(\text{crs}, x, w) = \text{false}), st)</math></li> </ol>
--	--

Figure 9: Left: Game defining XT extractability of a proof system  $\Pi$  for a relation  $R$ . Right: The state initializer and oracle responder algorithms associated by the XT property specification  $\text{PS}_{R, S}^{\text{xt}}[\Pi]$  to proof system  $\Pi$ , where  $R$  is an NP-relation and  $S$  is a simulator.

TRANSFERENCE OF XT. We can now conclude the transference of XT as follows.

**Theorem 5.9** *Let  $R$  be an NP relation. Let  $D\Pi$  be a dual-mode proof system for relation  $R$  that is mode-indistinguishable, and let  $\mu \in \{0, 1\}$ . Assume  $D\Pi_\mu$  is XT for  $R$ . Then  $D\Pi_{1-\mu}$  is XT for  $R$ .*

**Proof of Theorem 5.9:** From the assumption that  $D\Pi_\mu$  is XT for  $R$ , we know that there exists an extractor  $S$  relative to which the function  $\lambda \mapsto \text{Adv}_{\Pi, R, S, \lambda}^{\text{xt}}(A)$  is negligible. From Proposition 5.8, we know that  $\text{Adv}_{D\Pi_\mu, R, S, \lambda}^{\text{xt}}(A) = \text{Adv}_{\text{PS}_{R, S}^{\text{xt}}[D\Pi_\mu], \lambda}^{\text{ps}}(A)$  and  $\text{Adv}_{D\Pi_{1-\mu}, R, S, \lambda}^{\text{xt}}(A) = \text{Adv}_{\text{PS}_{R, S}^{\text{xt}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(A)$ , where the XT property specification is as described in Figure 9. We also know from the definition of the XT property specification that it is a polynomial-time property specification. As a result, we can use the result of Theorem 5.2, that is, we can apply Equation (1) from the proof of Theorem 5.2 to this setting:

$$\text{Adv}_{\text{PS}_{R, S}^{\text{xt}}[D\Pi_{1-\mu}], \lambda}^{\text{ps}}(A) \leq \text{Adv}_{\text{PS}_{R, S}^{\text{xt}}[D\Pi_\mu], \lambda}^{\text{ps}}(A) + 2 \cdot \text{Adv}_{D\Pi, \lambda}^{\text{mode}}(A_\mu).$$

We can now use the mode indistinguishability property of  $D\Pi$  and the assumption that  $D\Pi_\mu$  is XT for  $R$  to conclude that  $D\Pi_{1-\mu}$  is XT for  $R$  (the same extractor  $S$  works for both modes).  $\blacksquare$

## 6 SND in application: A test case

The properties that one would most like to successfully transfer are the ones of most utility in applications. Since whether or not soundness transfers depends on exactly how it is defined (recall that SND-E transfers and SND-P does not) we would like to see which of the two is needed by applications. To this end we examine here in detail one representative and canonical application of NIZKs that uses soundness, namely the construction of a digital signature scheme from [BG90]. We find that the type of soundness needed is SND-P. SND-E does not appear to suffice. And

<p><b>Game <math>\mathbf{G}_{\text{DS},\lambda}^{\text{uf}}</math></b></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>(sk, vk) \leftarrow_{\\$} \text{DS.K}(1^\lambda)</math> ; Return <math>vk</math></li> </ol> <p>SIGN(<math>m</math>):</p> <ol style="list-style-type: none"> <li>2 <math>\sigma \leftarrow_{\\$} \text{DS.S}(1^\lambda, sk, vk, m)</math></li> <li>3 <math>S \leftarrow S \cup \{m\}</math> ; Return <math>\sigma</math></li> </ol> <p>FIN(<math>m, \sigma</math>):</p> <ol style="list-style-type: none"> <li>4 <math>\text{vf} \leftarrow \text{DS.V}(1^\lambda, vk, m, \sigma)</math></li> <li>5 Return ( <math>\text{vf}</math> and ( <math>m \notin S</math> ) )</li> </ol>	<p><b>Game <math>\mathbf{G}_{\text{F},\lambda}^{\text{uf}}</math></b></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>K \leftarrow_{\\$} \{0, 1\}^\lambda</math></li> </ol> <p>FN(<math>m</math>):</p> <ol style="list-style-type: none"> <li>2 <math>S \leftarrow S \cup \{m\}</math> ; Return <math>\text{F}(1^\lambda, K, m)</math></li> </ol> <p>FIN(<math>m, T</math>):</p> <ol style="list-style-type: none"> <li>3 <math>\text{vf} \leftarrow (\text{F}(1^\lambda, K, m) = T)</math></li> <li>4 Return ( <math>\text{vf}</math> and ( <math>m \notin S</math> ) )</li> </ol>
<p><b>Game <math>\mathbf{G}_{\text{CS},\lambda}^{\text{bind}}</math></b></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>cp \leftarrow_{\\$} \text{CS.P}(1^\lambda)</math> ; Return <math>cp</math></li> </ol> <p>FIN(<math>K, d, K', d'</math>):</p> <ol style="list-style-type: none"> <li>2 If ( <math>K = K'</math> ) then return <b>false</b></li> <li>3 <math>c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)</math></li> <li>4 <math>c' \leftarrow \text{CS.C}(1^\lambda, cp, K', d')</math></li> <li>5 Return ( <math>c' = c</math> )</li> </ol>	<p><b>Game <math>\mathbf{G}_{\text{CS},\lambda}^{\text{hide}}</math></b></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>cp \leftarrow_{\\$} \text{CS.P}(1^\lambda)</math> ; <math>b \leftarrow_{\\$} \{0, 1\}</math></li> <li>2 Return <math>cp</math></li> </ol> <p>CMT(<math>K_0, K_1</math>):</p> <ol style="list-style-type: none"> <li>3 <math>d \leftarrow_{\\$} \{0, 1\}^\lambda</math></li> <li>4 <math>c \leftarrow \text{CS.C}(1^\lambda, cp, K_b, d)</math> ; return <math>c</math></li> </ol> <p>FIN(<math>b'</math>):</p> <ol style="list-style-type: none"> <li>5 Return ( <math>b' = b</math> )</li> </ol>

Figure 10: Top Left: Game defining UF security of a signature scheme DS. Top Right: Game defining UF security for MAC F. Middle: Games defining BIND and HIDE security for commitment scheme CS.

signatures do not seem like an anomaly in this regard; indeed it seems that applications usually require SND-P, not SND-E. This makes the transference position for these two more of a concern.

We slightly strengthen the results of [BG90]. While they relied on statistical soundness, we only assume computational (else the question of SND-P versus SND-E is moot due to Proposition 4.2), and we use a MAC rather than a PRF. We also generalize the underlying NIZK proof system to be in the designated-prover model. We can then capture the original CRS model setting by requiring the proving key  $k_P$  to be the empty string.

**DIGITAL SIGNATURES.** A (digital) signature scheme DS specifies PT algorithms for key-generation, signing and verifying, as follows. Via  $(sk, vk) \leftarrow_{\$} \text{DS.K}(1^\lambda)$ , the signer generates a secret signing key  $sk$  and public verification key  $vk$ . Via  $\sigma \leftarrow_{\$} \text{DS.S}(1^\lambda, sk, vk, m)$ , the signer generates a signature of a message  $m \in \{0, 1\}^*$ . Via  $\text{vf} \leftarrow \text{DS.V}(1^\lambda, vk, m, \sigma)$ , the verifier deterministically generates a boolean decision as to the validity of  $\sigma$ . Correctness requires that  $\text{DS.V}(1^\lambda, vk, m, \sigma) = \text{true}$  for all  $\lambda \in \mathbb{N}$ , all  $\sigma \in [\text{DS.S}(1^\lambda, sk, vk, m)]$ , all  $(sk, vk) \in [\text{DS.K}(1^\lambda)]$  and all  $m \in \{0, 1\}^*$ .

The security metric is unforgeability (UF) [GMR88]. The game is in Figure 10. We let  $\mathbf{Adv}_{\text{DS},\lambda}^{\text{uf}}(\mathbf{A}) = \Pr[\mathbf{G}_{\text{DS},\lambda}^{\text{uf}}(\mathbf{A})]$  be the uf-advantage of adversary A. A signature scheme DS is said to be UF-secure if for all PT adversaries A, the function  $\lambda \mapsto \mathbf{Adv}_{\text{DS},\lambda}^{\text{uf}}(\mathbf{A})$  is negligible.

**BUILDING BLOCKS.** We give definitions for the building blocks we need, namely MACs and commitment schemes.

A MAC is a PT deterministic algorithm F that takes  $1^\lambda$ , a key  $K \in \{0, 1\}^\lambda$  and an input  $m \in \{0, 1\}^*$  to return an output  $\text{F}(1^\lambda, K, m) \in \{0, 1\}^*$ . The security metric is again unforgeability: A MAC is the symmetric analogue of a signature scheme. Consider the game  $\mathbf{G}_{\text{F},\lambda}^{\text{uf}}$  in Figure 10. The uf-advantage of adversary A is  $\mathbf{Adv}_{\text{F},\lambda}^{\text{uf}}(\mathbf{A}) = \Pr[\mathbf{G}_{\text{F},\lambda}^{\text{uf}}(\mathbf{A})]$ . We say that F is UF-secure if for

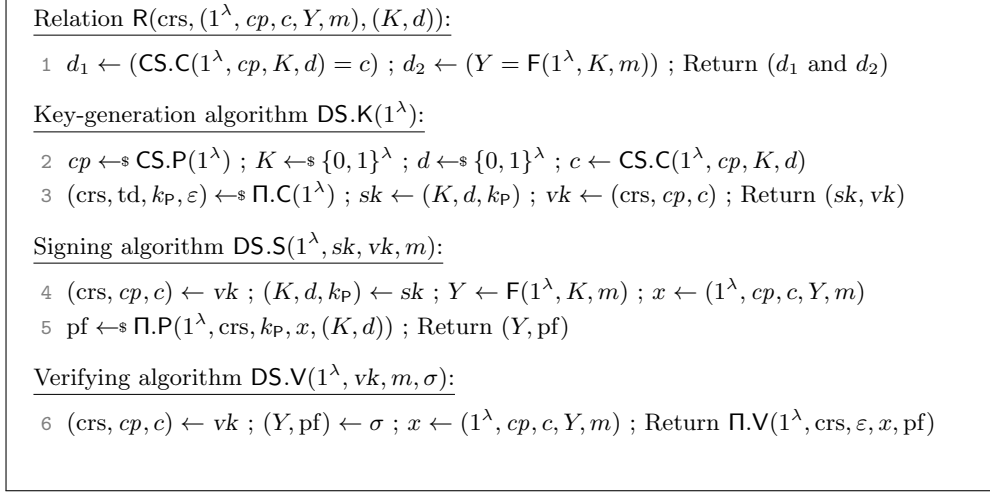

Figure 11: The relation  $R$  and the digital signature scheme  $\text{DS}$  for Theorem 6.1.

all PT adversaries  $A$ , the function  $\lambda \mapsto \mathbf{Adv}_{F, \lambda}^{\text{uf}}(A)$  is negligible.

A commitment scheme  $\text{CS}$  specifies a PT parameter generation algorithm  $\text{CS.P}$  and a deterministic commitment algorithm  $\text{CS.C}$  such that  $\text{CS.C}(1^\lambda, cp, \cdot, \cdot): \{0, 1\}^* \times \{0, 1\}^\lambda \rightarrow \{0, 1\}^*$  for all  $\lambda \in \mathbb{N}$  and for every  $cp \in [\text{CS.P}(1^\lambda)]$ . The scheme is set up by generating parameters  $cp \leftarrow_{\$} \text{CS.P}(1^\lambda)$ . Then via  $c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)$ , one generates a commitment to string  $K \in \{0, 1\}^*$  with randomly-chosen de-commitment key  $d \leftarrow_{\$} \{0, 1\}^\lambda$ . The bind advantage of an adversary  $A$  is  $\mathbf{Adv}_{\text{CS}, \lambda}^{\text{bind}}(A) = \Pr[\mathbf{G}_{\text{CS}, \lambda}^{\text{bind}}(A)]$ , where the game is in Figure 10. It is required that the  $d, d'$  queried by the adversary to  $\text{FIN}$  are in  $\{0, 1\}^\lambda$ . We require perfect binding, namely that  $\mathbf{Adv}_{\text{CS}, \lambda}^{\text{bind}}(A) = 0$  for all adversaries  $A$ , regardless of their running time. The hide advantage of an adversary  $A$  is  $\mathbf{Adv}_{\text{CS}, \lambda}^{\text{hide}}(A) = 2 \Pr[\mathbf{G}_{\text{CS}, \lambda}^{\text{hide}}(A)] - 1$ , where the game is in Figure 10. We say that  $\text{CS}$  is hiding if for all PT  $A$  the function  $\lambda \mapsto \mathbf{Adv}_{\text{CS}, \lambda}^{\text{hide}}(A)$  is negligible. (The hiding requirement is computational.)

CONSTRUCTION. With MAC  $F$  and commitment scheme  $\text{CS}$  as above, let  $R$  be the relation of Figure 11. Then let  $\Pi$  be a proof system that satisfies completeness,  $\text{SND-P}$  for  $R$  and  $\text{ZK}$  for  $R$ , and let  $\text{DS}$  be the signature scheme whose algorithms are shown in Figure 11. Theorem 6.1 says that  $\text{DS}$  is UF secure. The proof of this theorem is in Appendix C.

**Theorem 6.1** *Let  $F$  be a UF-secure MAC. Let  $\text{CS}$  be a commitment scheme that is perfectly binding and (computationally) hiding. Let  $R$  be the relation of Figure 11. Let  $\Pi$  be a proof system that is  $\text{SND-P}$  and  $\text{ZK}$  for  $R$ . Let  $\text{DS}$  be the signature scheme whose algorithms are shown in Figure 11. Then  $\text{DS}$  is UF-secure.*

The question that we now discuss is whether the  $\text{SND-E}$  soundness notion will suffice for this application. Recall that  $\text{SND-E}$  requires adversaries to be membership-conscious. However, in a reduction from an adversary to an adversary against  $\text{SND-E}$ , there is no clear way to ensure that membership-consciousness holds, which indicates that  $\text{SND-E}$  might not be sufficient for this application.

Figure 13: More adversaries for the proof of Proposition 4.3.

## A Proof of Proposition 4.3

In this appendix, we provide a counterexample to prove the separation between SND-E and SND-P in the computational setting.

**Proof of Proposition 4.3:** Consider a proof system  $\Pi$  for the relation  $R$ , both of which are described in Figure 12. We show that (1)  $\Pi$  is SND-E for  $R$  but (2)  $\Pi$  is not SND-P for  $R$ , assuming DDH is hard relative to the group generator.

We provide an adversary strategy to show (2) in Figure 12. When  $\mu = 1$ , the adversary always wins the SND-P game, and when  $\mu = 0$ , it wins the SND-P game with negligible probability. Therefore, we can conclude that:

$$\mathbf{Adv}_{\Pi, R, \lambda}^{\text{snd-p}}(A_{\text{snd-p}}) \geq \frac{1}{2}$$

We now show (1) via a sequence of games, described in Figure 12. First, notice that  $\mathbf{Adv}_{\Pi, R, \lambda}^{\text{snd-e}}(A) = \Pr[G_0(A)]$ . Further, we have

$$\Pr[G_0(A)] = \Pr[G_1(A)] + \Pr[G_2(A)] + \Pr[G_3(A)] + \Pr[G_4(A)]$$

We can construct adversaries  $A_{\text{ddh}}^1$  and  $A_{\text{ddh}}^2$  against the DDH game (described in Figure 13) such

that

$$\begin{aligned}\Pr[G_2(A)] - \Pr[G_1(A)] &\leq \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(A_{\text{ddh}}^1) \\ \Pr[G_4(A)] - \Pr[G_3(A)] &\leq \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(A_{\text{ddh}}^2)\end{aligned}$$

We can further write

$$\begin{aligned}\Pr[G_1(A)] &= \Pr[G_5(A)] + \Pr[G_6(A)] \\ \Pr[G_3(A)] &= \Pr[G_7(A)] + \Pr[G_8(A)]\end{aligned}$$

We can see that

$$\Pr[G_6(A)] \leq \mathbf{Adv}_{\mathbf{R},\lambda,\Pi,\mathbf{C},\Pi,\mathbf{V}}^{\text{mcg}}(A), \quad \Pr[G_8(A)] \leq \mathbf{Adv}_{\mathbf{R},\lambda,\Pi,\mathbf{C},\Pi,\mathbf{V}}^{\text{mcg}}(A).$$

Now, since the adversary  $A$  must be membership-conscious for the relation  $\mathbf{R}$  (i.e.  $A \in \mathcal{A}_{\mathbf{R}}^{\text{mc}}$ ), we can infer that

$$\Pr[G_6(A)] \leq \text{negl}(\lambda), \quad \Pr[G_8(A)] \leq \text{negl}(\lambda).$$

We also construct adversaries  $A_{\text{cdh}}^1$  and  $A_{\text{cdh}}^2$  against the CDH game in [Figure 13](#) such that

$$\Pr[G_5(A)] \leq \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{cdh}}(A_{\text{cdh}}^1), \quad \Pr[G_7(A)] \leq \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{cdh}}(A_{\text{cdh}}^2).$$

Putting all this together, we get

$$\begin{aligned}\mathbf{Adv}_{\Pi,\mathbf{R},\lambda}^{\text{snd-e}}(A) &\leq \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(A_{\text{ddh}}^1) + \mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{ddh}}(A_{\text{ddh}}^2) \\ &\quad + 2\mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{cdh}}(A_{\text{cdh}}^1) + 2\mathbf{Adv}_{\mathbf{GG},\lambda}^{\text{cdh}}(A_{\text{cdh}}^2) + \text{negl}(\lambda)\end{aligned}$$

This shows that the scheme is SND-E secure assuming the hardness of the DDH and CDH assumptions relative to the group generator.  $\blacksquare$

## B Proof of Theorem 5.2

**Proof of Theorem 5.2:** Let  $A$  be a polynomial-time adversary. We build a polynomial-time adversary  $A_\mu$  such that for all  $\lambda \in \mathbb{N}$  we have

$$\mathbf{Adv}_{\text{PS}[\text{D}\Pi_{1-\mu}],\lambda}^{\text{ps}}(A) \leq \mathbf{Adv}_{\text{PS}[\text{D}\Pi_\mu],\lambda}^{\text{ps}}(A) + 2 \cdot \mathbf{Adv}_{\text{D}\Pi,\lambda}^{\text{mode}}(A_\mu). \quad (1)$$

The theorem follows.

To establish Equation (1), recall that, as per the definition of a property specification, the oracle responder algorithm depends only on the prover and verifier algorithms of the proof system it is given, invoking these as oracles. But, by the definition of the proof systems induced proof by a dual-mode proof system, for both  $\text{D}\Pi_0$  and  $\text{D}\Pi_1$ , the prover algorithm is  $\text{D}\Pi.\text{P}$  and the verifier algorithm is  $\text{D}\Pi.\text{V}$ . This means that the oracle responder algorithms corresponding to  $\text{D}\Pi_0$  and  $\text{D}\Pi_1$  are identical, both being  $\text{PS}[\text{D}\Pi.\text{P}, \text{D}\Pi.\text{V}].\text{Or}$ .

With this, consider the games  $G_d$ , defined, for  $d \in \{0, 1\}$ , in [Figure 14](#). At line 1, they generate the CRS and the proving and verification keys in mode  $d$ , and then run the state initializer (we use here the fact that it does not depend on the proof system) to get an initial state. In responding to OR queries at line 2, they use the oracle responder with prover and verifier algorithms set to those

<p><u>Game <math>G_d</math> // <math>d \in \{0, 1\}</math></u></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}, \text{td}, k_P, k_V) \leftarrow \text{D}\Pi.\text{C}(1^\lambda, d)</math> ; <math>st \leftarrow \text{PS.Stl}(1^\lambda, \text{crs}, k_P, k_V)</math></li> </ol> <p>OR(Oname, Oarg):</p> <ol style="list-style-type: none"> <li>2 <math>(\text{Orsp}, st) \leftarrow \text{PS}[\text{D}\Pi.\text{P}, \text{D}\Pi.\text{V}].\text{Or}(\text{Oname}, \text{Oarg})</math></li> <li>3 If <math>((\text{Oname} = \text{Fin}) \text{ and } (\text{out} = \perp))</math> then <math>\text{out} \leftarrow \text{Orsp}</math></li> <li>4 Return Orsp</li> </ol> <p>FIN():</p> <ol style="list-style-type: none"> <li>5 Return <math>\text{out}</math></li> </ol>
<p><u>Adversary <math>A_\mu</math></u></p> <ol style="list-style-type: none"> <li>1 <math>(\text{crs}, k_P, k_V) \leftarrow \text{G}_{\text{D}\Pi, \lambda}^{\text{mode}}.\text{INIT}</math> ; <math>st \leftarrow \text{PS.Stl}(1^\lambda, \text{crs}, k_P, k_V)</math> ; Run <math>A^{\text{OR}}</math></li> <li>2 If <math>\text{out}</math> then <math>a \leftarrow 1</math> else <math>a \leftarrow 0</math></li> <li>3 Return <math>(a \oplus \mu)</math></li> </ol> <p>OR(Oname, Oarg):</p> <ol style="list-style-type: none"> <li>4 <math>(\text{Orsp}, st) \leftarrow \text{PS}[\text{D}\Pi.\text{P}, \text{D}\Pi.\text{V}].\text{Or}(\text{Oname}, \text{Oarg})</math></li> <li>5 If <math>((\text{Oname} = \text{Fin}) \text{ and } (\text{out} = \perp))</math> then <math>\text{out} \leftarrow \text{Orsp}</math></li> <li>6 Return Orsp</li> </ol>

Figure 14: Top: Games for the proof of Theorem 5.2. Bottom: Adversary for the proof of Theorem 5.2.

of the dual-mode proof system, as per the above. Then for both  $d = 0$  and  $d = 1$  we have

$$\mathbf{Adv}_{\text{PS}[\text{D}\Pi_d], \lambda}^{\text{ps}}(A) = \begin{cases} \Pr[G_d(A)] & \text{if type} = \text{ser} \\ 2 \Pr[G_d(A)] - 1 & \text{if type} = \text{dec}. \end{cases}$$

Thus if  $\text{type} = \text{ser}$  we have

$$\begin{aligned} \mathbf{Adv}_{\text{PS}[\text{D}\Pi_{1-\mu}], \lambda}^{\text{ps}}(A) &= \Pr[G_{1-\mu}(A)] = \Pr[G_\mu(A)] + (\Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)]) \\ &= \mathbf{Adv}_{\text{PS}[\text{D}\Pi_\mu], \lambda}^{\text{ps}}(A) + (\Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)]). \end{aligned}$$

And if  $\text{type} = \text{dec}$  we have

$$\begin{aligned} \mathbf{Adv}_{\text{PS}[\text{D}\Pi_{1-\mu}], \lambda}^{\text{ps}}(A) &= 2 \Pr[G_{1-\mu}(A)] - 1 \\ &= 2 \Pr[G_\mu(A)] - 1 + 2 \cdot (\Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)]) \\ &= \mathbf{Adv}_{\text{PS}[\text{D}\Pi_\mu], \lambda}^{\text{ps}}(A) + 2 \cdot (\Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)]). \end{aligned}$$

We build PT mode indistinguishability adversary  $A_{\text{mode}}$  so that

$$\Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)] \leq \mathbf{Adv}_{\text{D}\Pi, \lambda}^{\text{mode}}(A_\mu).$$

The adversary  $A_\mu$  is shown at the bottom in Figure 14. At line 1 it obtains a CRS and proving and verification keys from its own INIT oracle. It then runs  $A$  and simulates the OR oracle of the latter as shown. Let  $b$  be the randomly chosen bit in  $\mathbf{G}_{\text{D}\Pi, \lambda}^{\text{mode}}$ . Then

$$\mathbf{Adv}_{\text{D}\Pi, \lambda}^{\text{mode}}(A_\mu) = \Pr[a \oplus \mu = 1 \mid b = 1] - \Pr[a \oplus \mu = 1 \mid b = 0].$$

Let us consider the two cases depending on whether  $\mu$  is 0 or 1.

$$\begin{aligned} \underline{\mu = 0} : \quad \mathbf{Adv}_{\mathcal{D}\Pi, \lambda}^{\text{mode}}(A_0) &= \Pr[a = 1 \mid b = 1] - \Pr[a = 1 \mid b = 0] \\ &= \Pr[G_1(A)] - \Pr[G_0(A)] \end{aligned}$$

$$\begin{aligned} \underline{\mu = 1} : \quad \mathbf{Adv}_{\mathcal{D}\Pi, \lambda}^{\text{mode}}(A_1) &= \Pr[a = 0 \mid b = 1] - \Pr[a = 0 \mid b = 0] \\ &= \Pr[a = 1 \mid b = 0] - \Pr[a = 1 \mid b = 1] \\ &= \Pr[G_0(A)] - \Pr[G_1(A)] \end{aligned}$$

We can combine the two cases together as follows:

$$\mathbf{Adv}_{\mathcal{D}\Pi, \lambda}^{\text{mode}}(A_\mu) = \Pr[G_{1-\mu}(A)] - \Pr[G_\mu(A)] .$$

This completes the proof.  $\blacksquare$

## C Proof of Theorem 6.1

**Proof of Theorem 6.1:** Let  $A_{\mathcal{D}\mathcal{S}}$  be a polynomial time adversary. Then we construct PT adversaries  $A_{\text{sndp}}, A_{\text{zk}}, A_{\text{hide}}, A_{\text{uf}}$  (shown explicitly in Figures 16 and 17) such that

$$\begin{aligned} \mathbf{Adv}_{\mathcal{D}\mathcal{S}, \lambda}^{\text{uf}}(A_{\mathcal{D}\mathcal{S}}) &\leq \mathbf{Adv}_{\Pi, \mathcal{R}, \lambda}^{\text{snd-p}}(A_{\text{sndp}}) + \mathbf{Adv}_{\Pi, \mathcal{R}, \mathcal{S}, \lambda}^{\text{zk}}(A_{\text{zk}}) \\ &\quad + \mathbf{Adv}_{\mathcal{C}\mathcal{S}, \lambda}^{\text{hide}}(A_{\text{hide}}) + \mathbf{Adv}_{\mathcal{F}}^{\text{uf}}(A_{\text{uf}}) . \end{aligned}$$

The theorem then follows.

Consider the games of Figure 15. Games  $G_0, G_1, G_2$  differ only in one line, the ones used, respectively, in these games, being lines 8,9,10, which change how the game decides whether or not the adversary's forgery attempt should let it win the game. We have

$$\begin{aligned} \mathbf{Adv}_{\mathcal{D}\mathcal{S}}^{\text{uf}}(A_{\mathcal{D}\mathcal{S}}) &= \Pr[G_0(A_{\mathcal{D}\mathcal{S}})] \\ &= \Pr[G_1(A_{\mathcal{D}\mathcal{S}})] + (\Pr[G_0(A_{\mathcal{D}\mathcal{S}})] - \Pr[G_1(A_{\mathcal{D}\mathcal{S}})]) . \end{aligned}$$

We claim to have designed the Figure 16 adversary  $A_{\text{sndp}}$  so that

$$\Pr[G_0(A_{\mathcal{D}\mathcal{S}})] - \Pr[G_1(A_{\mathcal{D}\mathcal{S}})] \leq \mathbf{Adv}_{\Pi, \mathcal{R}, \lambda}^{\text{snd-p}}(A_{\text{sndp}}) .$$

Notice first that the condition setting  $\text{vf}$  in  $G_1$  (line 8) is exactly the test for membership in  $\mathcal{L}_{\mathcal{R}}(\text{crs})$ . For brevity, we let  $x$  denote the  $(1^\lambda, cp, c, Y, m)$  tuple corresponding to the  $(m, \sigma)$  pair queried to the  $\text{FIN}$  procedure by the adversary  $A_{\mathcal{D}\mathcal{S}}$  in games  $G_0$  and  $G_1$ . Then

$$\Pr[G_0(A_{\mathcal{D}\mathcal{S}})] = \Pr[\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf})] \text{ and } \Pr[G_1(A_{\mathcal{D}\mathcal{S}})] = \Pr[x \in \mathcal{L}_{\mathcal{R}}(\text{crs})] .$$

<p><u>Games <math>G_0, G_1, G_2</math></u></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>cp \leftarrow \text{CS.P}(1^\lambda)</math> ; <math>K \leftarrow \{0, 1\}^\lambda</math> ; <math>d \leftarrow \{0, 1\}^\lambda</math> ; <math>c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)</math></li> <li>2 <math>(\text{crs}, \text{td}, \varepsilon, \varepsilon) \leftarrow \Pi.C(1^\lambda)</math> ; <math>vk \leftarrow (\text{crs}, cp, c)</math> ; return <math>vk</math></li> </ol> <p>SIGN(<math>m</math>):</p> <ol style="list-style-type: none"> <li>3 <math>Y \leftarrow F(1^\lambda, K, m)</math> ; <math>\text{pf} \leftarrow \Pi.P(1^\lambda, \text{crs}, \varepsilon, (1^\lambda, cp, c, Y, m), (K, d))</math></li> <li>4 <math>\sigma \leftarrow (Y, \text{pf})</math> ; <math>S \leftarrow S \cup \{m\}</math> ; Return <math>\sigma</math></li> </ol> <p>FIN(<math>m, \sigma</math>):</p> <ol style="list-style-type: none"> <li>5 <math>(Y, \text{pf}) \leftarrow \sigma</math></li> <li>6 If <math>(m \in S)</math> then return <b>false</b></li> <li>7 <math>\text{vf} \leftarrow \Pi.V(1^\lambda, \text{crs}, \varepsilon, (1^\lambda, cp, c, Y, m), \text{pf})</math> // Game <math>G_0</math></li> <li>8 <math>\text{vf} \leftarrow \exists(K', d') : (\text{CS.C}(1^\lambda, cp, K', d') = c) \wedge (F(1^\lambda, K', m) = Y)</math> // Game <math>G_1</math></li> <li>9 <math>\text{vf} \leftarrow (F(1^\lambda, K, m) = Y)</math> // Game <math>G_2</math></li> <li>10 Return <math>\text{vf}</math></li> </ol>
<p><u>Games <math>G_3, G_4</math></u></p> <p>INIT():</p> <ol style="list-style-type: none"> <li>1 <math>cp \leftarrow \text{CS.P}(1^\lambda)</math> ; <math>K, K' \leftarrow \{0, 1\}^\lambda</math> ; <math>d \leftarrow \{0, 1\}^\lambda</math> ; <math>(\text{crs}, \text{td}, \varepsilon) \leftarrow \text{S.C}(1^\lambda)</math></li> <li>2 <math>c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)</math> // Game <math>G_3</math></li> <li>3 <math>c \leftarrow \text{CS.C}(1^\lambda, cp, K', d)</math> // Game <math>G_4</math></li> <li>4 <math>vk \leftarrow (\text{crs}, cp, c)</math> ; return <math>vk</math></li> </ol> <p>SIGN(<math>m</math>):</p> <ol style="list-style-type: none"> <li>5 <math>Y \leftarrow F(1^\lambda, K, m)</math> ; <math>\text{pf} \leftarrow \text{S.P}(1^\lambda, \text{crs}, \text{td}, \varepsilon, (1^\lambda, cp, c, Y, m))</math></li> <li>6 <math>\sigma \leftarrow (Y, \text{pf})</math> ; <math>S \leftarrow S \cup \{m\}</math> ; Return <math>\sigma</math></li> </ol> <p>FIN(<math>m, \sigma</math>):</p> <ol style="list-style-type: none"> <li>7 <math>(Y, \text{pf}) \leftarrow \sigma</math></li> <li>8 If <math>(m \in S)</math> then return <b>false</b></li> <li>9 <math>\text{vf} \leftarrow (F(1^\lambda, K, m) = Y)</math> ; Return <math>\text{vf}</math></li> </ol>

Figure 15: Games for proof of Theorem 6.1.

This gives us (let  $\chi = \Pr[G_0(A_{\text{DS}})] - \Pr[G_1(A_{\text{DS}})]$ )

$$\begin{aligned}
\chi &= \Pr[\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf})] - \Pr[x \in L_R(\text{crs})] \\
&= \Pr[\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) \wedge (x \notin L_R(\text{crs}))] \\
&\quad + \Pr[\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) \wedge (x \in L_R(\text{crs}))] - \Pr[(x \in L_R(\text{crs}))] \\
&\leq \Pr[\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) \wedge (x \notin L_R(\text{crs}))] \\
&= \mathbf{Adv}_{\Pi, R, \lambda}^{\text{snd-p}}(A_{\text{sndp}})
\end{aligned}$$

We now show by explicitly providing the adversaries  $A_{\text{zk}}$ ,  $A_{\text{hide}}$ , and  $A_{\text{uf}}$ , that

$$\Pr[G_1(A_{\text{DS}})] \leq \mathbf{Adv}_{\Pi, R, S, \lambda}^{\text{zk}}(A_{\text{zk}}) + \mathbf{Adv}_{\text{CS}, \lambda}^{\text{hide}}(A_{\text{hide}}) + \mathbf{Adv}_{\text{F}}^{\text{uf}}(A_{\text{uf}}) . \quad (2)$$

We have

$$\Pr[G_1(A_{\text{DS}})] = \Pr[G_2(A_{\text{DS}})] + (\Pr[G_1(A_{\text{DS}})] - \Pr[G_2(A_{\text{DS}})]) .$$

Adversary $A_{zk}$ :	Adversary $A_{sndp}$ :
1 $cp \leftarrow \text{CS.P}(1^\lambda)$ ; $K \leftarrow \{0, 1\}^\lambda$ ; $d \leftarrow \{0, 1\}^\lambda$ 2 $(\text{crs}, \varepsilon) \leftarrow \mathbf{G}_{\Pi, R, S, \lambda}^{zk} \cdot \text{INIT}$ ; $c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)$ 3 $vk \leftarrow (\text{crs}, cp, c)$ ; $A_{ds}^{\text{INIT, SIGN, FIN}}$	1 $cp \leftarrow \text{CS.P}(1^\lambda)$ ; $K \leftarrow \{0, 1\}^\lambda$ 2 $d \leftarrow \{0, 1\}^\lambda$ ; $c \leftarrow \text{CS.C}(1^\lambda, cp, K, d)$ 3 $(1^\lambda, \text{crs}, k_p) \leftarrow \mathbf{G}_{\Pi, R, \lambda}^{\text{snd-p}} \cdot \text{INIT}$ 4 $vk \leftarrow (\text{crs}, cp, c)$ ; $A_{DS}^{\text{INIT, SIGN, FIN}}$
<b>INIT:</b> 4 Return $vk$	<b>INIT:</b> 5 Return $vk$
<b>SIGN(<math>m</math>):</b> 5 $Y \leftarrow \mathbf{F}(1^\lambda, K, m)$ 6 $\text{pf} \leftarrow \mathbf{G}_{\Pi, R, S, \lambda}^{zk} \cdot \text{PF}((1^\lambda, cp, c, Y, m), (K, d))$ 7 $\sigma \leftarrow (Y, \text{pf})$ ; $S \leftarrow S \cup \{m\}$ ; Return $\sigma$	<b>SIGN(<math>m</math>):</b> 6 $Y \leftarrow \mathbf{F}(K, m)$ ; $x \leftarrow (1^\lambda, cp, c, Y, m)$ 7 $\text{pf} \leftarrow \mathbf{\Pi.P}(1^\lambda, \text{crs}, k_p, x, (K, d))$ 8 Return $(Y, \text{pf})$
<b>FIN(<math>m, \sigma</math>):</b> 8 $(Y, \text{pf}) \leftarrow \sigma$ 9 If $(m \in S)$ then $\mathbf{G}_{\Pi, R, S, \lambda}^{zk} \cdot \text{FIN}(0)$ 10 If $(\mathbf{F}(1^\lambda, K, m) = Y)$ then $b' \leftarrow 1$ else $b' \leftarrow 0$ 11 $\mathbf{G}_{\Pi, R, S, \lambda}^{zk} \cdot \text{FIN}(b')$	<b>FIN(<math>m, \sigma</math>):</b> 9 $(Y, \text{pf}) \leftarrow \sigma$ ; $\mathbf{G}_{\Pi, R, \lambda}^{\text{snd-p}} \cdot \text{VF}((1^\lambda, cp, c, Y, m), \text{pf})$ 10 $\mathbf{G}_{\Pi, R, \lambda}^{\text{snd-p}} \cdot \text{FIN}()$

Figure 16: Adversaries for the proof of Theorem 6.1.

The assumption that CS is perfectly binding implies that

$$\Pr[G_1(A_{DS})] = \Pr[G_2(A_{DS})] .$$

Next we have

$$\Pr[G_2(A_{DS})] = \Pr[G_3(A_{DS})] + (\Pr[G_2(A_{DS})] - \Pr[G_3(A_{DS})]) .$$

We claim to have designed the Figure 16 adversary  $A_{zk}$  so that

$$\Pr[G_2(A_{DS})] - \Pr[G_3(A_{DS})] \leq \mathbf{Adv}_{\Pi, R, S, \lambda}^{zk}(A_{zk}) .$$

Next we have

$$\Pr[G_3(A_{DS})] = \Pr[G_4(A_{DS})] + (\Pr[G_3(A_{DS})] - \Pr[G_4(A_{DS})]) .$$

We claim to have designed the Figure 17 adversaries  $A_{\text{hide}}$  and  $A_{\text{uf}}$  so that

$$\Pr[G_3(A_{DS})] - \Pr[G_4(A_{DS})] \leq \mathbf{Adv}_{\text{CS}, \lambda}^{\text{hide}}(A_{\text{hide}}) ,$$

$$\Pr[G_4(A_{DS})] \leq \mathbf{Adv}_{\text{F}}^{\text{uf}}(A_{\text{uf}}) .$$

Putting these together gives us the inequality (2).

This completes the proof.  $\blacksquare$

## D Related Work

It has been shown that non-interactive zero-knowledge proof systems for languages outside of **BPP** cannot exist in the plain model [GO94]. The existing literature instead considers a variety of different models under which they provide constructions achieving non-interactive zero knowledge.

THE COMMON REFERENCE STRING (CRS) MODEL. This widely used model is also known as the auxiliary string model [Dam00] or the public-parameter model [FF00, Ps05]. In this model, there

Adversary $A_{\text{hide}}$ :	Adversary $A_{\text{uf}}$ :
1 $cp \leftarrow \mathbf{G}_{\text{CS},\lambda}^{\text{hide}}.\text{INIT} ; K, K' \leftarrow \{0, 1\}^\lambda$	1 $cp \leftarrow \text{CS.P}(1^\lambda) ; K' \leftarrow \{0, 1\}^\lambda$
2 $c \leftarrow \mathbf{G}_{\text{CS},\lambda}^{\text{hide}}.\text{CMT}(K, K')$	2 $d \leftarrow \{0, 1\}^\lambda ; (\text{crs}, \text{td}, \varepsilon) \leftarrow \text{S.C}(1^\lambda)$
3 $(\text{crs}, \text{td}, \varepsilon) \leftarrow \text{S.C}(1^\lambda)$	3 $c \leftarrow \text{CS.C}(1^\lambda, cp, K', d)$
4 $vk \leftarrow (\text{crs}, cp, c) ; A_{\text{ds}}^{\text{INIT},\text{SIGN},\text{FIN}}$	4 $vk \leftarrow (\text{crs}, cp, c)$
INIT:	5 $\mathbf{G}_{\text{F},\lambda}^{\text{uf}}.\text{INIT} ; A_{\text{ds}}^{\text{INIT},\text{SIGN},\text{FIN}}$
5 Return $vk$	INIT:
SIGN( $m$ ):	6 Return $vk$
6 $S \leftarrow S \cup \{m\} ; Y \leftarrow \text{F}(1^\lambda, K, m)$	SIGN( $m$ ):
7 $x \leftarrow (1^\lambda, cp, c, Y, m)$	7 $Y \leftarrow \mathbf{G}_{\text{F},\lambda}^{\text{uf}}.\text{FN}(m)$
8 $\text{pf} \leftarrow \text{S.P}(1^\lambda, \text{crs}, \text{td}, \varepsilon, x)$	8 $x \leftarrow (1^\lambda, cp, c, Y, m)$
9 $\sigma \leftarrow (Y, \text{pf}) ; \text{return } \sigma$	9 $\text{pf} \leftarrow \text{S.P}(1^\lambda, \text{crs}, \text{td}, \varepsilon, x)$
FIN( $m, \sigma$ ):	10 Return $(Y, \text{pf})$
10 $(Y, \text{pf}) \leftarrow \sigma$	FIN( $m, \sigma$ ):
11 If $(m \in S)$ then $\mathbf{G}_{\text{CS},\lambda}^{\text{hide}}.\text{FIN}(0)$	11 $(Y, \text{pf}) \leftarrow \sigma ; \mathbf{G}_{\text{F},\lambda}^{\text{uf}}.\text{FIN}(m, Y)$
12 If $((\text{F}(1^\lambda, K, m) = Y))$ then $b' \leftarrow 1$	
13 Else $b' \leftarrow 0$	
14 $\mathbf{G}_{\text{CS},\lambda}^{\text{hide}}.\text{FIN}(b')$	

Figure 17: More adversaries for the proof of Theorem 6.1.

is assumed to exist a trusted party that generates a common reference string which is available to both the prover and the verifier. The common random string model [BFM90] can be considered to be a special case of the CRS model, in which the common string generated by the trusted party is sampled from a uniform distribution.

THE PREPROCESSING MODEL [DMP90]. In this model, there is assumed to be an initial, statement-independent trusted setup (preprocessing) phase, that results in the generation of a proving key (which will be needed to generate proofs) and a verification key (which is needed to verify proofs). Soundness is now required to hold even against a prover with oracle access to the verifier (but no access to the verification key), while zero-knowledge is required to hold against a verifier with oracle access to the prover (but no access to the proving key).

THE DESIGNATED VERIFIER AND DESIGNATED PROVER MODELS.

The designated verifier (DV) model (introduced in [JSI96] for interactive proofs and in [ES02, PsV06, DFN06] for non-interactive proofs) and the designated prover (DP) model [KW18, KNY19] can be studied as special cases of the preprocessing model. In the DV model, the proving key is considered to be empty, so that any party can generate a proof of a statement, but verification can only be done by the party with the secret verification key. Analogously, in the DP model, the verification key is considered to be empty, so that any party can verify a proof of a statement, but proof generation can only be done by the party with the secret proving key.

DUAL-MODE NIZKS. The abstraction of the dual-mode cryptosystem was first considered in [PVW08] for the setting of oblivious transfer. A similar technique named “parameter switching” was used in [GOS06b] in the context of non-interactive zero-knowledge. Though this technique was used in multiple constructions [Gro06, GOS06a, GOS06b, GS08], the term “dual-mode NIZK” was first used in [AFH<sup>+</sup>16] as one of the building blocks for multilinear maps. Dual-mode NIZKs have been constructed from obfuscation in [HU19], while [LPWW20] constructs dual-mode NIZKs in

the designated verifier model from different assumptions. The works of [CCH<sup>+</sup>19, PS19] also construct NIZK systems that can be used in two modes, but do not explicitly consider the dual-mode abstraction.

We now examine the definitions of soundness in papers that use the dual-mode within our notation to see whether they transfer. Let  $R$  be a relation and  $\Pi$  a proof system.

[GOS06B]. They call their definition non-adaptive computational soundness. It requires that for all non-uniform PT adversaries  $A$  and all  $x \notin L_R$  (the language here does not depend on the CRS)—

$$\Pr \left[ (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_s \Pi.C(1^\lambda) ; \text{pf} \leftarrow_s A(x, \text{crs}) : \Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false} \right] \approx 1 .$$

The “ $\approx 1$ ” above is shorthand for saying there is a negligible function  $\nu$  such that the probability on the left is  $\geq 1 - \nu(\lambda)$ . Now there is some ambiguity in the definition, namely that it is not clear how  $\nu$  is quantified. Does it depend on  $A$ ? On  $x$ ? The meaningful choice here is to assume the authors meant it to depend on  $A$  but not on  $x$ , so that the definition becomes that for all non-uniform PT adversaries  $A$  there exists a negligible function  $\nu$  such that for all  $x \notin L_R$  and all  $\lambda$ —

$$\Pr \left[ (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_s \Pi.C(1^\lambda) ; \text{pf} \leftarrow_s A(x, \text{crs}) : \Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{true} \right] \leq \nu(\lambda) .$$

This notion of soundness does transfer. The proof relies, however, crucially on non-uniformity; mode indistinguishability must be assumed for non-uniform adversaries. This, however, is indeed the setting of the paper, so we conclude that soundness as per [GOS06b] transfers successfully, supporting the claim made (without explicit proof) in the paper.

However, this non-adaptive definition of soundness is not well suited (too weak) for some applications, because it does not allow  $x$  to depend on the CRS. This arises for example in the application to signatures we discussed in Section 6 . Also the definition does not seem written to allow dependence of the language on the CRS, yet in their system to prove that a ciphertext encrypts a bit, the language does depend on the CRS.

[GOS06A, GRO06, GS08, HHNR17]. All of these works use equivalent definitions for (perfect) soundness for a non-interactive proof system  $\Pi$  for relation  $R$ . They require that for all non-uniform adversaries  $A$  and all  $\lambda$ —

$$\Pr \left[ \begin{array}{l} (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_s \Pi.C(1^\lambda); \\ (x, \text{pf}) \leftarrow_s A(\text{crs}) \end{array} : \Pi.V(1^\lambda, \text{crs}, x, \text{pf}) = \text{false if } x \notin L_R(\text{crs}) \right] = 1 .$$

The computational variant would presumably be that for all non-uniform PT adversaries  $A$  there exists a negligible function  $\nu$  such that for all  $\lambda$ —

$$\Pr \left[ \begin{array}{l} (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_s \Pi.C(1^\lambda); \\ (x, \text{pf}) \leftarrow_s A(\text{crs}) \end{array} : \Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false if } x \notin L_R(\text{crs}) \right] \geq 1 - \nu(\lambda) .$$

Again, there is some ambiguity, namely as to the meaning of the “if.” We would expect that what is written after the colon, here “ $\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false if } x \notin L_R(\text{crs})$ ,” is an event in the probability space described by what precedes the colon, and in this light have trouble understanding the “if.” Our best interpretation was to view the “if” as an implication. That is, “ $\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false if } x \notin L_R(\text{crs})$ ” becomes “ $(x \notin L_R(\text{crs})) \implies (\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false})$ ,” which in turn becomes “ $(\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{false}) \text{ or } (x \in L_R(\text{crs}))$ .” The condition above now becomes

$$\Pr \left[ \begin{array}{l} (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_s \Pi.C(1^\lambda); \\ (x, \text{pf}) \leftarrow_s A(\text{crs}) \end{array} : (\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{true}) \wedge (x \notin L_R(\text{crs})) \right] \leq \nu(\lambda) .$$

This definition is equivalent to the SND-P notion of soundness we give in [Figure 3](#). As we have shown in [Theorem 4.4](#), this notion of soundness need not in general transfer, so that the soundness definition of [\[GOS06a, Gro06, GS08, HHNR17\]](#) also fails in general to transfer. Note [Theorem 4.4](#) holds in both the uniform and non-uniform settings; unlike for the [\[GOS06b\]](#) definition discussed above, non-uniformity does not seem aid transfer here. All this is with the caveat that we may be mis-interpreting the “if.”

On the other hand, the soundness in this definition is adaptive, making it good for applications, as we indicate via [Section 6](#). The pattern we see is that weak (less application-enabling) soundness transfers and strong (more application-enabling) soundness does not transfer.

[\[AFH<sup>+</sup>16, FHHL18\]](#). This work uses a definition of perfect soundness for a non-interactive proof system. Their definition implies that for all  $\lambda$ —

$$\Pr \left[ \begin{array}{l} (\text{crs}, \text{td}, \varepsilon, \varepsilon) \leftarrow_{\$} \Pi.C(1^\lambda); \\ (x, \text{pf}) \leftarrow_{\$} A(\text{crs}) \end{array} : (\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{true}) \wedge (x \notin L_R(\text{crs})) \right] = 0.$$

This corresponds to the SND-P notion of soundness, which, as we have seen, does not in general transfer. However, the definition (and its computational variant, which is not defined in the paper) is adaptive, which is application-enabling.

[\[HU19\]](#). Their requirement of (statistical) soundness is that for all non-uniform adversaries  $A$  there exists a negligible function  $\nu$  such that—

$$\Pr \left[ \begin{array}{l} (\text{crs}, \varepsilon, \varepsilon, \varepsilon) \leftarrow_{\$} \Pi.C(1^\lambda); \\ (x, \text{pf}) \leftarrow_{\$} A(\text{crs}) \end{array} : (\Pi.V(1^\lambda, \text{crs}, \varepsilon, x, \text{pf}) = \text{true}) \wedge (x \notin L_R(\text{crs})) \right] \leq \nu(\lambda).$$

The computational version is presumably that for all PT non-uniform adversaries there exists a negligible function  $\nu$  such that for all  $\lambda$  the same equation above holds. This definition is equivalent to the SND-P notion of soundness we define in [Figure 3](#). As we have shown in [Theorem 4.4](#), this notion of soundness does not in general transfer. However it is a strong, application-enabling definition.

[\[CCH<sup>+</sup>19, PS19\]](#) These works consider two definitions of soundness, in the statistical case and in the computational case. The statistical soundness definition is the stronger, adaptive version, and corresponds to the SND-P notion of soundness in [Figure 3](#). However, computational soundness has a weaker, non-adaptive definition (corresponding to the SND-E notion). This corresponds implicitly to our result that the transference would only hold for the weaker SND-E notion but not for the SND-P notion.

[\[LPWW20\]](#). Note that this work, unlike the previous works, is in the designated-verifier model. It too, defines two forms of soundness, an adaptive version, and a non-adaptive version and points out the difficulty in arguing what corresponds to the transference of the SND-P notion. It therefore uses the weaker non-adaptive version for computational soundness.
