The most efficient indifferentiable hashing to elliptic curves of $j$-invariant 1728

Dmitrii Koshelev

Computer sciences and networks department, Télécom Paris

Abstract. This article contains a new hash function (indifferentiable from a random oracle) to any ordinary elliptic curve $E_a: y^2 = x^3 + ax$ (of invariant 1728) over a finite field $\mathbb{F}_q$. Its advantage consists in the necessity to compute (in constant time) only one exponentiation in $\mathbb{F}_q$, at least for the most practical case $q \equiv 5 \pmod{8}$. In comparison, for such a $q$ the previous fastest constant-time indifferentiable hash functions to $E_a$ require to compute two exponentiations in $\mathbb{F}_q$. By the way, the famous Shallue–van de Woestijne hash function (acting as a random oracle) performs four exponentiations in $\mathbb{F}_q$ even when it is implemented as efficiently as possible. Since it is highly unlikely that there is a hash function to an elliptic curve without exponentiations at all (even if it is supersingular), the result of the given article seems to be unimprovable.

Key words: Calabi–Yau threefolds, double-odd elliptic curves, elliptic fibrations, indifferentiable hashing to elliptic curves, $j$-invariant 1728, pairing-based cryptography, quartic residue symbol and quartic roots, rational surfaces, Weil–Aubry–Perret inequality.

1 Introduction

Let $\mathbb{F}_q$ be a finite field of char($\mathbb{F}_q$) > 3 and $E_a: y^2 = x^3 + ax$ be an elliptic $\mathbb{F}_q$-curve whose the $j$-invariant equals 1728. The curves $E_a$ are considered with interest in elliptic cryptography at least at the research level. The point is that (apart from elliptic curves of $j = 0$) they have a non-trivial automorphism group, which leads to more efficient scalar multiplication and pairing computation on them (see details in [1, §6.2.2, §3.3.2] respectively). This paper focuses on ordinary curves, because supersingular ones pose special challenges for security of discrete logarithm cryptography by virtue of [1, Remark 2.22]. And according to [2, Example V.4.5] the ordinariness of $E_a$ results in the restriction $q \equiv 1 \pmod{4}$, i.e., $i := \sqrt{-1} \in \mathbb{F}_q$.

Examples of pairing-friendly curves of $j = 1728$ are represented, e.g., in [1, §4.5.2]. Curiously, unlike curves of $j$-invariant 0, some curves $E_a$ (for example, do255e from [3, §5.2]) can be so-called double-odd elliptic curves [3], [4], that is their order equals two times an odd (prime) number. Double-odd curves are a trade off between prime order curves and twisted Edwards curves [1, §6.4.1] (whose the cofactor is always a multiple of four). Thus double-odd curves enjoy simpler subgroup membership testing than twisted Edwards ones and, at the same time, faster complete addition formulas than prime order ones. These notions are discussed in the remarkable article [5] and in references therein.

Many cryptographic protocols (e.g., the popular aggregate BLS signature [6]) use a hash function of the form $H: \{0, 1\}^* \to E_a(\mathbb{F}_q)$. And if it is necessary, the value of $H$ can be
subsequently moved into a prime order subgroup of $E_a(\mathbb{F}_q)$ by clearing the cofactor [7, §7]. There is the regularly updated draft [7] (see also the slightly outdated source [1, §8]) on the topic of hashing to elliptic curves. Due to [7, §10] it is highly desirable and often inevitable that $H$ is *indifferentiable from a random oracle* in sense of Maurer et al. [8, §4.2]. By the way, [3, §3.7] raises the question of efficient indifferentiable hashing to curves $E_a$, but that article does not answer this question in an acceptable way.

Almost all such previously proposed hash functions are obtained as the composition $H := e^{\otimes 2} \circ h$ of a hash function $h : \{0, 1\}^* \to \mathbb{F}_q^2$ and the *tensor square*

$$e^{\otimes 2} : \mathbb{F}_q^2 \to E_a(\mathbb{F}_q) \quad e^{\otimes 2}(t_0, t_1) := e(t_0) + e(t_1)$$

for some map $e : \mathbb{F}_q \to E_a(\mathbb{F}_q)$. Such a map is often called *encoding*. For the given $H$ its indifferentiability follows from [9, Theorem 1] if $h$ is indifferentiable and $e^{\otimes 2}$ is *admissible* in the sense of [9, Definition 4]. It is worth noting that the admissibility property in particular requires an encoding $e$ to be constant-time, that is, informally speaking, the computation time of its value is independent of an input argument.

The previous state-of-the-art encoding, valid for any curve $E_a$, is proposed by the author in [10] after a refinement of the work [11]. This encoding $e$ (resp. $e^{\otimes 2}$) can be implemented by extracting one (resp. two) square root(s) in $\mathbb{F}_q$. In comparison, an optimized version of the classical *Shallue–van de Woestijne (SW) encoding* [12] (resp. $e^{\otimes 2}_{SW}$) extracts two (resp. four) square roots in $\mathbb{F}_q$. This fact is folklore among implementers of elliptic cryptography (cf. [13, §4.2]). As is customary (see, e.g., [1, §5.1.7]), a square root is expressed via one exponentiation in $\mathbb{F}_q$ at least when $q \not\equiv 1 \pmod{8}$. Taking into account the condition $q \equiv 1 \pmod{4}$, we obtain $q \equiv 5 \pmod{8}$.

This work (also for any $a \in \mathbb{F}_q^*$) directly provides an admissible map $h : \mathbb{F}_q^2 \to E_a(\mathbb{F}_q)$, which requires to extract one quartic root in $\mathbb{F}_q$. We will show that for $q \equiv 5 \pmod{8}$ this operation is also nothing but one exponentiation in $\mathbb{F}_q$. In other words, the tensor square is actually superfluous for curves $E_a$ and hence we get rid of one (resp. three) exponentiation(s) in $\mathbb{F}_q$ in comparison with $e^{\otimes 2}$ (resp. $e^{\otimes 2}_{SW}$). Moreover, it is worth emphasizing that $h$ is given by quite simple formulas with small coefficients. Therefore the new result seems interesting both from theoretical and practical points of view.

By definition, pairings act from two groups traditionally denoted by $\mathbb{G}_1$, $\mathbb{G}_2$. As said in [1, §3.2.5], in practice, $\mathbb{G}_1 \subset E_a(\mathbb{F}_q)$ for a prime $q$ and $\mathbb{G}_2 \subset E'_{a'}(\mathbb{F}_{q^n})$ for some $n \in \mathbb{N}$ and $a' \in \mathbb{F}_q^*$. Moreover, the extension degree $n$ is often even. In this case, due to [1, §Algorithm 5.18] a square root in $\mathbb{F}_{q^n}$ can be expressed via two square roots in $\mathbb{F}_{q^{n/2}}$. To our knowledge, there is no analogous expression for a quartic root in $\mathbb{F}_{q^n}$. So, unlike $e$, the new map $h$ is not relevant for hashing to $\mathbb{G}_2$ whenever $2 \mid n$. Fortunately, as explained in [14, §1.2], in combination with clearing the (large) cofactor $\#E_{a'}(\mathbb{F}_{q^n})/\#\mathbb{G}_2$ it is sufficient to apply $e : \mathbb{F}_{q^n} \to E'_{a'}(\mathbb{F}_{q^n})$ only once. Thus the best solution is always to utilize the map $h$ (resp. $e$) in the case of $\mathbb{G}_1$ or the whole group $E_a(\mathbb{F}_q)$ (resp. $\mathbb{G}_2$).

An approach to produce $h$ is based on an explicit $\mathbb{F}_q$-parametrization $\varphi : \mathbb{A}^2 \to T$ of a (uni-)rational $\mathbb{F}_q$-surface [15, §4.9] on some algebraic threefold $T$, that is $\dim(T) = 3$. Then $h$ is just the composition of $\varphi$ (restricted to $\mathbb{F}_q$-points) and an auxiliary map $h' : T(\mathbb{F}_q) \to E_a(\mathbb{F}_q)$. More concretely, there is an *elliptic fibration* $E \to \mathbb{A}^2$ (see, e.g., [16, §2]). The desired $\varphi$ is immediately obtained from an infinite order $\mathbb{F}_q$-section $\psi : \mathbb{A}^2 \to E$ of this fibration.
Ideologically, the described approach is almost the same as in [17], but, of course, with different technique details (for example, $T = \mathcal{E}$ in [17]). There provided that $\sqrt{b} \in \mathbb{F}_q$ the author constructs one more admissible map from $\mathbb{F}_q^2$ to the $\mathbb{F}_q$-point group of an elliptic curve $y^2 = x^3 + b$ (of $j$-invariant 0). Moreover, this map equally performs only one exponentiation in $\mathbb{F}_q$, namely a cubic root extraction.

Another threefold underlies the SW encoding, although a rational $\mathbb{F}_q$-curve (of geometric genus 0) is taken on it instead of a unirational $\mathbb{F}_q$-surface. Fortunately, in [18, Lemma 3] Skalba provides such a surface and hence a (probably, admissible) map $\mathbb{F}_q^2 \to E(\mathbb{F}_q)$ for any elliptic $\mathbb{F}_q$-curve $E$ of $j(E) \neq 0$. Unfortunately, in the literature the Skalba map is not as famous as the SW encoding. Nevertheless, like $e_{SW}$, this map still needs to extract two square roots in $\mathbb{F}_q$.

Interestingly, all the threefolds, appeared in the given scientific domain, turn out to be Calabi–Yau varieties, which are applied over the field $\mathbb{C}$ in theoretical physics (see, e.g., [19]). However since we will work over non-closed fields it is also reasonable to cite a source (such as [20]) on the arithmetic of Calabi–Yau varieties. It is worth noting that one-dimensional Calabi–Yau varieties are exactly elliptic curves. So it is not surprising that their high-dimensional analogue occurs in the context of elliptic cryptography.

2 Geometric results

As said in the introduction, throughout the article we assume that $i := \sqrt{-1} \in \mathbb{F}_q$. Consequently, the curve $E_a : y^2 = x^3 + ax$ possesses the $\mathbb{F}_q$-automorphism $[i](x, y) := (-x, iy)$ of order 4. Obviously, $E_a[2] = \{ \mathcal{O}, P_0, P_{\pm} \}$, where
\[
\mathcal{O} := (0 : 1 : 0), \quad P_0 := (0, 0), \quad P_{\pm} := (\pm i\sqrt{a}, 0).
\]
Besides, any two $\mathbb{F}_q$-curves of $j = 1728$ are isomorphic (at most over $\mathbb{F}_q^4$) by means of the map
\[
\sigma_{a,a'} : E_a \cong E_{a'}, \quad \sigma_{a,a'}(x, y) := (\alpha^2 x, \alpha^3 y),
\]
where $\alpha := \sqrt[4]{a'/a}$. As a result, up to an $\mathbb{F}_q$-isomorphism, there are exactly 4 twists for $E_a$, namely $E_{ac}$ for $j \in \mathbb{Z}/4$ and $c \in \mathbb{F}_q^\times \setminus (\mathbb{F}_q^*)^2$.

It is suggested to consider the $\mathbb{F}_q$-threefold
\[
T := \left\{ S_0 : y_0^2 = x_0^3 + ax(t^3 + at)x_0, \quad S_1 : y_1^2 = x_1^3 + \alpha^3x(t^3 + at)x_1 \subset \mathbb{A}^5_{(x_0, x_1, y_0, y_1, t)} \right\}.
\]
It seems that $T$ is birationally $\mathbb{F}_q$-isomorphic to the quotient of $A := E_a \times E_{ac} \times E_{ac^3}$ by the order 4 diagonal automorphism $\delta := [-1] \times [i] \times [i]$. This quotient is similar to the one from [17, Lemma 1]. Since the given fact is not necessary for our purposes, we do not prove it. However, this is a useful observation, because $age(\delta) = 1$ (as well as for the automorphism $[\omega]^3$ from [17, §1]), where the age is defined in [21]. So by virtue [21, Theorem 13] the quotient $A/\delta$ enjoys at least a rational curve over the algebraic closure $\overline{\mathbb{F}}_q$. Thus there is a justified hope of obtaining a rational $\mathbb{F}_q$-surface on $T$.

Curiously, our $T$ (like the one from [17, Lemma 1]) can be also interpreted as a Schoen threefold [22], that is the fiber product [23, §4.5] of two rational elliptic surfaces with a section
where the variables $y_0$, $y_1$ are of the weight 2. Further, on the affine chart $t \neq 0$ the threefold $T$ possesses the form
\begin{align*}
T = \{ & y_0^2 = x_0^3 y_2 + a c(t^2 + a t y_2^2)x_0, \\
& y_1^2 = x_1^3 y_2 + a c^3(t^3 + a t y_2^2)x_1 \} \subset \mathbb{P}(1, 1, 2, 2, 1, 1),
\end{align*}
where the variables $y_0$, $y_1$ are of the weight 2. Thus we have the birational isomorphisms
\begin{align*}
\tau: V \cong T & \quad \tau := \left( \frac{u_0}{v_2}, \frac{u_1}{v_2}, \frac{v_0}{v_2}, \frac{v_1}{v_2}, \frac{1}{v_2} \right), \quad \tau^{-1}: T \cong V \quad \tau^{-1} = \left( \frac{x_0}{t^2}, \frac{x_1}{t^2}, \frac{y_0}{t^2}, \frac{y_1}{t^2} \right).
\end{align*}

We can look at $V$ as a curve in $\mathbb{A}^3(\nu_0, \nu_1, \nu_2)$ given by the intersection of two quadratic surfaces over the rational function field $F_q(\nu_0, \nu_1)$. The existence of an $F_q(\nu_0, \nu_1)$-point on $V$ is not clear, hence we apply the base change $\chi: u_j := ct_j^2$, which leads to
\begin{align*}
\mathcal{E} := \{ & v_0^2 = c^3 t_0^6 v_2 + a c^2(1 + a v_2^2)t_0^2, \\
& v_1^2 = c^3 t_1^6 v_2 + a c^4(1 + a v_2^2)t_1^2 \} \subset \mathbb{A}^5_{(t_0, t_1, \nu_0, \nu_1, \nu_2)}.
\end{align*}

For the sake of compactness, put $F := F_q(t_0, t_1)$. At infinity, i.e., in $F^3 \setminus \mathbb{A}^3(\nu_0, \nu_1, \nu_2)$ there are on $E$ the $F$-points
\begin{align*}
\mathcal{P}_\pm := (\pm a c t_0 : a c^2 t_1 : 1 : 0).
\end{align*}

It is proposed to take $\mathcal{P}_+$ as the neutral element in the Mordell–Weil group $\mathcal{E}(F)$.

We will rely on some Magma calculations [26] that can be verified in the free calculator on the official site of this computer algebra system. The next lemmas are proved by means of the reduction to a Weierstrass form of $\mathcal{E}$.

**Lemma 1** ([26]). The $F$-curve $\mathcal{E}$ is elliptic with the $j$-invariant
\begin{align*}
j(\mathcal{E}) = \frac{16(c^2 t_0^8 t_1^8 + 12a^3 c^4 t_0^8 - 32a^3 c^2 t_0^4 t_1^4 + 12a^3 t_1^8 + 16a^6 c^2)^3}{a^3 ((c^2 t_0^8 - 4a^3)(c t_0^2 + t_1^2)(c t_0^2 - t_1^2)(t_1^8 - 16a^3 c^2))^2}.
\end{align*}

**Lemma 2** ([26]). The coordinates of the point $\psi := 2\mathcal{P}_-$ are the fractions $v_j(t_0, t_1) := \text{num}_j/\text{den}$, where
\begin{align*}
\text{num}_0 & := ac(-3c^4 t_0^8 + 2c^2 t_0^4 t_1^4 + t_1^8 + 16a^3 c^2)t_0, & \text{num}_1 & := ac^2(c^4 t_0^8 + 2c^2 t_0^4 t_1^4 - 3t_1^8 + 16a^3 c^2)t_1, \\
\text{num}_2 & := c^4 t_0^8 - 2c^2 t_0^4 t_1^4 + t_1^8 - 16a^3 c^2, & \text{den} & := 8a^2 c(c^2 t_0^4 + t_1^4).
\end{align*}
Further, we need the algebraic curves $C_i$; instance, it is suggested to resort to this system to establish the absolute irreducibility of the proof we tacitly use Magma in order to avoid awkward symbolic computations (see [26]). For where

$$\sqrt{b} \in \mathbb{F}_q$$

of degrees 2 and 4 respectively. Proof.

Theorem 1. For $v \in \mathbb{F}_q$ and $j \in \mathbb{Z}/2$ we will need the following $\mathbb{F}_q$-curves on $\mathbb{A}^2_{(t_0,t_1)}$:

$$C_j := \text{num}_j/t_j, \quad C_{2,v} := \text{num}_2 - v \cdot \text{den}, \quad C_{\infty} := \text{den}, \quad D_{j,x} := t_j^4 \cdot \text{num}_2 \cdot \text{den} - c^{2j-1} x^2 (a \cdot \text{num}_2^2 + \text{den}^2), \quad L_j := t_j.$$

(1)

For uniformity, $L_2 := \mathbb{P}^2 \setminus \mathbb{A}^2_{(t_0,t_1)}$. Incidentally, the $\mathbb{F}_q^2$-involution $(t_0,t_1) \mapsto (t_1/\sqrt{c}, t_0 \sqrt{c})$ gives the isomorphisms $C_j \cong C_{j+1}$ and $D_{j,x} \cong D_{j+1,x}$. Notice that always

$$\deg(C_j) = \deg(C_{2,v}) = 8, \quad \deg(C_{\infty}) = 4, \quad \deg(D_{j,x}) = 16$$

and in accordance with [27, §2.3.3] the arithmetic genera equal

$$p_a(C_j) = p_a(C_{2,v}) = 21, \quad p_a(C_{\infty}) = 3, \quad p_a(D_{j,x}) = 105.$$  

(3)

In the degenerate cases we obtain

$$C_{2,0} = F_+ \cup F_-, \quad C_{2,\pm \beta} = \bigcup_{j,k \in \mathbb{Z}/2} Q_{j,k,\pm}, \quad C_{\infty} = \bigcup_{j,k \in \mathbb{Z}/2} L_{j,k},$$

(4)

where $\beta := (i \sqrt{a})^{-1}$ and

$$F_{\pm} := c^2 t_0^4 - t_1^4 \pm 4a \sqrt{ac}, \quad L_{j,k} := (-1)^j \sqrt{(-1)^{k} i c \cdot t_0} + t_1,$$

$$Q_{j,k,\pm} := ct_0^2 + (-1)^j t_1^2 + (-1)^k 2 \sqrt{\pm c \sqrt{-a^3}}.$$  

The curves $F_{\pm}$ are nothing but Fermat quartics, hence they are non-singular of genus 3. By the way, all the lines $L_{j,k}$ intersect at the origin $(0,0)$.

Theorem 1. For $v \notin \{0, \pm \beta\}$, $x \notin \{0, \pm i \sqrt{a}\}$ the curves $C_j$, $C_{2,v}$, $D_{j,x}$ are absolutely irreducible.

Proof. Since $C_0 \cong \mathbb{P}_x^2$, $C_1$ and $D_{0,x} \cong \mathbb{P}_x^2$, $D_{1,x}$, it is sufficient to pick $j = 0$. Throughout the proof we tacitly use Magma in order to avoid awkward symbolic computations (see [26]). For instance, it is suggested to resort to this system to establish the absolute irreducibility of $C_0$. Further, we need the algebraic curves

$$C_{2,v}(t_0,t_1) := C_{2,v}(\sqrt{t_0}, \sqrt{t_1}), \quad D_{0,x}(t_0,t_1) := D_{0,x}(\sqrt{t_0}, \sqrt{t_1})$$

of degrees 2 and 4 respectively.
It is readily seen that the conic $C'_{2,v}$ enjoys the point $R := (1 : c^2 : 0) \in L_2$. The projection from it gives rise to the parametrization

\[ pr_R : C'_ {2,v} \simeq \mathbb{A}^1_s, \quad pr_R := \frac{c^2 t_0 - t_1}{c^2}, \quad \text{s.t.} \quad pr_R^{-1} : \mathbb{A}^1_s \simeq C'_ {2,v}, \quad pr_R^{-1} = (p_{0,v}, p_{1,v}), \]

where

\[ p_{0,v} := \frac{c^2 s^2 + 8a^2 cv - 16a^3}{16a^2 cv}, \quad p_{1,v} := \frac{c(c^2 s^2 - 8a^2 cv - 16a^3)}{16a^2 v}. \]

As a result, the curve $C''_{2,v} := \{ t_j^4 = p_{j,v} \}_{j=0}^1$ lying in $\mathbb{A}^3_{(t_0,t_1,s)}$ is birationally isomorphic to $C_{2,v}$ (in the sense of [23, §9.7]) by means of the projection $pr_{(t_0,t_1)}$. In particular, $C_{2,v}$ is absolutely irreducible if and only if $C''_{2,v}$ is so.

It can easily be checked that for $v \neq \pm \beta$ the discriminants of $p_{j,v} \in \overline{\mathbb{F}}_q[s]$ are non-zero. So $\sqrt{p_{0,v}} \notin K := \overline{\mathbb{F}}_q(s)$ and by virtue of [28, Proposition 3.7.3] the extension $K' := K(\sqrt[p_{0,v}]{r})$ is a Kummer one of degree 4. Also, the polynomials $p_{0,v}, p_{1,v}$ do not have common roots. Consequently, a root $r$ of $p_{1,v}$ is non-ramified in the extension $K'/K$. In other words, there are exactly 4 points $R_j := (i^2 \sqrt[p_{0,v}]{r}, r) \in \mathbb{A}^2_{(t_0,s)}$ over $r$ and the equalities $\nu_{R_j}(p_{1,v}) = \nu_r(p_{1,v}) = 1$ hold for the discrete valuations. Let’s apply Eisenstein’s irreducibility theorem [28, Proposition 3.1.15.(1)] to the polynomial $t_1 - p_{1,v} \in K'[t_1]$ and any point $R_j$. Recall that $C''_{2,v}$ always has the total fraction ring [23, §11.10]. In fact, we have just shown that this ring $\overline{\mathbb{F}}_q(C''_{2,v}) = K'(\sqrt[p_{1,v}]{s})$ is a field. As is well known, this is equivalent to the absolute irreducibility of $C''_{2,v}$.

Now we proceed to a similar proof in the case of $D_{0,x}$, but intermediate cumbersome formulas will be omitted for brevity. The quartic $D'_{0,x}$ is birationally isomorphic to the non-degenerate conic

\[ Q_x := t_0^2 + (a + x^2)t_1^2 + a(a + x^2) \subset \mathbb{A}^2_{(t_0,t_1)} \]

through an anticanonical map $\varphi_{-\text{can}} : D'_{0,x} \simeq Q_x$. Note that $Q_x$ has the point $R := (0, i\sqrt{a})$ and, as usual, the projection from it yields a parametrization $pr_R : Q_x \simeq \mathbb{A}^1_s$. It turns out that the map

\[ (pr_R \circ \varphi_{-\text{can}})^{-1} : \mathbb{A}^1_s \simeq D'_{0,x} \quad s \mapsto (f_{0,x}, f_{1,x}) \]

is given by the functions $f_{j,x} := A_{j,x}/B_x$ such that

\[ A_{0,x} := 4i\sqrt{a}x^2(a + x^2)s^2, \quad B_x := c(s^4 - (a + x^2)^2), \]

\[ A_{1,x} := 4i\sqrt{a}c^2(as^4 + 2\sqrt{a}(a + x^2)s^3 + (a + x^2)(2a + x^2)s^2 + 2\sqrt{a}(a + x^2)^2s + a(a + x^2)^2). \]

As a result, the curve $D''_{0,x} := \{ B_xt_j^4 = A_{j,x} \}_{j=0}^1$ lying in $\mathbb{A}^3_{(t_0,t_1,s)}$ is birationally isomorphic to $D_{0,x}$ by means of the projection $pr_{(t_0,t_1)}$. In particular, $D_{0,x}$ is absolutely irreducible if and only if $D''_{0,x}$ is so.

It is shown that

\[ \text{Res}(A_{1,x}, B_x) = 2^8 a^2 c^{12} x^6 (x^2 + a)^8 (x^2 - 8a), \quad \Delta(A_{1,x}) = -2^{16} a^7 c^{12} x^2 (a + x^2)^6 (x^2 - 8a), \]

where $\text{Res}$, $\Delta$ stand for the resultant and discriminant respectively. So we restrict ourselves to $x \notin \{0, \pm i\sqrt{a}, \pm 2\sqrt{2a}\}$. Since trivially $\sqrt[t_0]{f_{0,x}} \notin K := \overline{\mathbb{F}}_q(s)$, the extension $K' := K(\sqrt[t_0]{f_{0,x}})$ is a Kummer one of degree 4. The polynomials $A_{0,x}, A_{1,x}, B_x$ do not have common roots in pairs.
Consequently, a root $r$ of $A_{1,x}$ is non-ramified in the extension $K'/K$. In other words, there are exactly 4 points $R_j := (i^j \sqrt[3]{f_0,3}(r), r) \in \mathbb{A}_F^2$ over $r$ and the equalities $\nu_{R_j}(f_{1,x}) = \nu_r(f_{1,x}) = 1$ hold for the discrete valuations. As above, it remains to apply Eisenstein's irreducibility theorem to the polynomial $t^4_1 - f_{1,x} \in K'[t_1]$ and any point $R_j$. Finally, the case $x = \pm 2\sqrt{2a}$ is immediately processed by Magma. \hfill \Box

## 3 New hash function

This section clarifies how the rational $\mathbb{F}_q$-map $\varphi := \tau \circ \chi \circ \psi : \mathbb{A}_F^2 \rightarrow T$ (from the previous one) results in a constant-time map $h : (\mathbb{F}_q)^2 \rightarrow E_a(\mathbb{F}_q)$. First of all, for an element $\gamma \in \mathbb{F}_q^*$ denote by $(\frac{\gamma}{q}) = \gamma^{(q-1)/4}$ the quartic residue symbol [29, §4.B], which is evidently a group homomorphism $\mathbb{F}_q^* \rightarrow \{i^j\}_{j=0}^3$. Note that $(\frac{\gamma}{q}) = \pm 1$ if and only if $\sqrt[4]{\gamma} \in \mathbb{F}_q$. Moreover, $(\frac{\gamma}{q}) = 1$ if and only if $\sqrt[4]{\gamma} \in \mathbb{F}_q$.

To be definite, we assign $i := (\frac{\gamma}{q})$ for a fixed quadratic non-residue $c \in \mathbb{F}_q^*$. Also, for the sake of compactness, let $f := t^3 + at$ and hence $T = \{y_j^2 = x_j^3 + ac^{j+1}f x_j\}_{j=0}^3$. Notice that the isomorphism $\sigma_{ac^{j+1},a}$ is defined over $\mathbb{F}_q$ whenever $(\frac{\gamma}{q}) = (1)^{j+1}i$. One of crucial components of $h$ is the auxiliary map

$$h' : T(\mathbb{F}_q) \rightarrow E_a(\mathbb{F}_q), \quad h'(x_0, x_1, y_0, y_1, t) := \begin{cases} (t, \sqrt[4]{f}) & \text{if } \sqrt[4]{f} \in \mathbb{F}_q, \\ \sigma_{ac^{j+1},a}(x_0, y_0) & \text{if } (\frac{\gamma}{q}) = -i, \\ \sigma_{ac^{3j+1},a}(x_1, y_1) & \text{if } (\frac{\gamma}{q}) = i. \end{cases}$$

Unfortunately, in this form the value of $h'$ is computed no faster than using two exponentiations in $\mathbb{F}_q$: the first for $(\frac{\gamma}{q})$ and the second for $\sqrt[4]{f}$, $\sqrt[4]{c f}$, or $\sqrt[4]{c^3 f}$ respectively. Instead, below we give an equivalent definition of $h'$ (up to the automorphisms $[j]$), where $j \in \mathbb{Z}/4$.

We will restrict ourselves to the case $q \equiv 5 \mod 8$ justified in the introduction. The next lemma is useful itself.

**Lemma 3.** Consider the numbers

$$(r, n, k) := \begin{cases} (1, \frac{3q+1}{16}, \frac{q-5}{16}) & \text{if } q \equiv 5 \mod 16, \\ (3, \frac{q+3}{16}, \frac{q-13}{16}) & \text{if } q \equiv 13 \mod 16. \end{cases}$$

For $\gamma \in \mathbb{F}_q^*$ and $\theta := \gamma^n$ we have $\theta^4 = (\frac{\gamma}{q}) = \gamma$. In particular, $\sqrt[4]{\gamma} \in \mathbb{F}_q$ if and only if $\theta^4 = \gamma$. Moreover, for $\gamma = u/v$ (with $u, v \in \mathbb{F}_q^*$) there are the equalities

$$\theta = \begin{cases} uv^3(u^3v^{13})^k & \text{if } q \equiv 5 \mod 16, \\ uv^{11}(uv^{15})^k & \text{if } q \equiv 13 \mod 16. \end{cases}$$

**Proof.** If $q \equiv 5 \mod 16$, then

$$\theta^4 = \gamma^4 = \gamma^{(3q+1)/4} = \gamma^{3(q-1)/4} \cdot \gamma = (\frac{\gamma}{q})^4 \cdot \gamma,$$
\[ \theta = (u/v)^n = u^n v^{q-1-n} = u \cdot u^{2k} v^{(13q-17)/16} = uv^3(u^3 v^{13})^k. \]

In turn, if \( q \equiv 13 \pmod{16} \), then
\[ \theta^4 = \gamma^{4n} = \gamma^{(q+3)/4} = \gamma^{(q-1)/4} \cdot \gamma = \left( \frac{\gamma}{q} \right)_4 \cdot \gamma, \]
\[ \theta = (u/v)^n = u^n v^{q-1-n} = u \cdot u^{k} v^{(15q-19)/16} = uv^{11}(uv^{15})^k. \]

The lemma is proved. \( \square \)

By the way, the substitution \( \gamma = i \) in this lemma gives \( \left( \frac{i}{q} \right)_4 = i^r \). At the same time, for \( \gamma = f \) (that is \( \theta = f^n \)) and \( j \in \mathbb{Z}/4 \) we obtain the criterions
\[ \left( \frac{f}{q} \right)_4 = i^{-jr} \iff \left( \frac{f}{q} \right)_4 = \left( \frac{i}{q} \right)_4^{-j} \iff \left( \frac{i^j f}{q} \right)_4 = 1 \iff \theta^4 = i^j f. \]

Therefore
\[ j \in \{0, 2\} \iff \sqrt{f} \in \mathbb{F}_q \iff \theta^4 = \pm f \iff \sqrt{f} = \theta^2/\sqrt{\pm 1}. \]

Further, when \( j \in \{1, 3\} \), the isomorphism \( \sigma_{ac^j f_a} \) is defined over \( \mathbb{F}_q \) if and only if
\[ \sqrt{c^j f} \in \mathbb{F}_q \iff \left( \frac{f}{q} \right)_4 = \left( \frac{c}{q} \right)_4^{-j} \iff \left( \frac{f}{q} \right)_4 = i^{-j} \iff \theta^4 = i^j f. \]

On the other hand, in accordance with Lemma 3 the condition \( \sqrt{c^j f} \in \mathbb{F}_q \) exactly means that \( \sqrt{c^j f} = d^j \theta \), where \( d := c^n \).

Thus \( h' \) can be represented in the form
\[ h'_m: T(\mathbb{F}_q) \rightarrow E_a(\mathbb{F}_q) \quad h'_m(x_0, x_1, y_0, y_1, t) = \begin{cases} [i]^m(t, \theta^2 \sqrt{\pm 1}) & \text{if } \theta^4 = \pm f, \\ \left( \frac{x_0}{(d\theta)^2}, \frac{y_0}{(d\theta)^3} \right) & \text{if } \theta^4 = i^r f, \\ \left( \frac{x_1}{(d\theta)^2}, \frac{y_1}{(d^3\theta)^3} \right) & \text{if } \theta^4 = -i^r f, \end{cases} \]
where \( m \in \mathbb{Z}/4 \). Obviously, the degenerate case \( f = \theta = 0 \) is processed by the first condition. More concretely, denote by \( m \) the position number of an element \( t_0 \in \mathbb{F}_q^* \) in the set \( \{i^j t_0\}_{j=0}^3 \) ordered with respect to some order in \( \mathbb{F}_q^* \). For example, if \( q \) is a prime, then this can be the usual numerical one. Finally, we come to the desired map
\[ h: (\mathbb{F}_q^*)^2 \rightarrow E_a(\mathbb{F}_q) \quad h(t_0, t_1) := \begin{cases} \mathcal{O} & \text{if } (\text{num}_2 \cdot \text{den})(t_0, t_1) = 0, \\ (h'_m \circ \varphi)(t_0, t_1) & \text{otherwise.} \end{cases} \]

It is worth emphasizing that due to Lemma 3 the value \( \theta \) can be computed with the cost of one exponentiation in \( \mathbb{F}_q \) even if \( f \) is given as a fraction. Besides, in the definition of \( h'_m \) the quartic residue symbol does not appear. Further, by returning the value of \( h \) in (weighted) projective coordinates (as preferred in practice [1, §2.3.2, §3.3.2]), we entirely avoid inversions in the field. Also, the constants \( i, d \) are found once at the precomputation stage. Calculating the value \( \theta \) every time no matter whether \( \text{num}_2 \cdot \text{den} \cdot f = 0 \) or not, we eventually obtain

**Remark 1.** At least when \( q \equiv 5 \pmod{8} \), the map \( h \) is computed in constant time of one exponentiation in \( \mathbb{F}_q \).
4 Indifferentiability from a random oracle

For the sake of compactness, we introduce the reducible curves

\[ D_x := C_{2,x^{-1}} \cup C_{2,-x^{-1}} \cup D_{0,x} \cup D_{1,x}, \quad C_O := C_{2,0} \cup C_{\infty}, \]
\[ C_{\pm} := C_0 \cup C_1 \cup C_{2,\beta} \cup C_{2,-\beta}, \quad L := L_0 \cup L_1 \cup L_2 \]

consisting of the curves (1).

**Theorem 2.** For any point \( P = (x, y) \in E_a(\mathbb{F}_q) \setminus E_a[2] \) we have

\[ h^{-1}(\{(i)^j(P)\}_{j=0}^3) = D_x(\mathbb{F}_q) \setminus L. \]

In turn,

\[ h^{-1}(O) = C_O(\mathbb{F}_q) \setminus L, \quad h^{-1}(P_0) = \emptyset, \quad \text{and} \quad h^{-1}\{P_{\pm}\} = C_{\pm}(\mathbb{F}_q) \setminus L \]

if \( \sqrt{a} \in \mathbb{F}_q \).

**Proof.** Recall that the encoding \( h \) is defined via \( \varphi = (x_0, x_1, y_0, y_1, t): \mathbb{A}_a^2(t_0, t_1) \rightarrow T \), where

\[ x_j = ct_j^2/v_2, \quad y_j = v_j/v_2^2, \quad t = v_2^{-1}, \quad v_0, v_1, v_2 \in \mathbb{F}_q(t_0, t_1). \]

We assume everywhere that \( t_j \in \mathbb{F}_q^* \).

First, the condition \( h(t_0, t_1) = O \) means by definition that \( (t_0, t_1) \in C_O \). Further, suppose that \( (x, 0) = h(t_0, t_1) \in E_a[2] \setminus \{O\} \). Then \( y_0y_1 = 0 \) (i.e., \( v_0v_1 = 0 \)) or \( f = 0 \) (i.e., \( t \in \{0, \pm i\sqrt{a}\} \)). The case \( x = 0 \) does not occur, because \( x_j, t \neq 0 \) (or, equivalently, \( t_j, \text{den} \neq 0 \)).

In turn, under the condition \( x = \pm i\sqrt{a} \in \mathbb{F}_q \) we obtain \( (t_0, t_1) \in C_{\pm} \) as stated in the theorem.

Now let’s study the general case \( P = (x, y) = h(t_0, t_1) \notin E_a[2] \). Whenever \( \sqrt{f} \in \mathbb{F}_q \), we have \( P = [i]m(t, \sqrt{f}) \). In other words, \( (t_0, t_1) \in C_{2,x^{-1}} \cup C_{2,-x^{-1}} \). Next, assume that \( \left(\frac{L}{q}\right)_4 = (-1)^{j+1}i \) and \( P = \sigma_{ac^{2j+1}f, a}(x_j, y_j) \). There is the sequence of criterions

\[ P = \sigma_{ac^{2j+1}f, a}(x_j, y_j) \iff x_j = \sqrt{c^{2j+1}f} \cdot x \iff ct_j^2 = v_2 \sqrt{c^{2j+1}f} \cdot x \iff t_j^4 = v_2c^{2j-1}(1 + av_2^2)x^2 \iff (t_0, t_1) \in D_{j,x}. \]

Thus \( P = h(t_0, t_1) \) if and only if \( (t_0, t_1) \in D_x \). \( \square \)

**Lemma 4.** For two \( \mathbb{F}_q \)-curves \( C, C' \subset \mathbb{P}^2 \) without common components there are the inequalities

\[ \#C(\mathbb{F}_q) + \#C'(\mathbb{F}_q) - \deg(C)\deg(C') \leq \#(C \cup C')(\mathbb{F}_q) \leq \#C(\mathbb{F}_q) + \#C'(\mathbb{F}_q). \]

Also, for \( C' = L \) we have

\[ \#C'(\mathbb{F}_q) - 3\deg(C) \leq \#(C \setminus L)(\mathbb{F}_q). \]
Proof. For the first part, it is sufficient to apply a weak version of Bezout’s theorem \([30, \S 5.3]\) and the inclusion-exclusion principle:

\[
\#(C \cap C')(\mathbb{F}_q) \leq \deg(C) \deg(C'), \quad \#(C \cup C')(\mathbb{F}_q) = \#C(\mathbb{F}_q) + \#C'(\mathbb{F}_q) - \#(C \cap C')(\mathbb{F}_q)
\]

Applying the trivial formula

\[
\#C(\mathbb{F}_q) - \#(C \cap L)(\mathbb{F}_q) = \#(C \setminus L)(\mathbb{F}_q)
\]

and Bezout’s theorem again, we get the second part. \(\square\)

**Corollary 1.** For any point \(P \in E_a(\mathbb{F}_q) \setminus E_a[2]\) we have

\[
\#h^{-1}(P) = \#h^{-1}(\{i\}(P)), \quad |\#h^{-1}(P) - q| \leq 126\sqrt{q} + 243.
\]

In turn,

\[
\#h^{-1}(\mathcal{O}) \leq 6q + 12\sqrt{q} + 3, \quad \#h^{-1}(P_0) = 0, \quad \text{and} \quad q - 42\sqrt{q} - 239 \leq \#h^{-1}(P_+) = \#h^{-1}(P_-) \leq 5q + 42\sqrt{q} + 5
\]

if \(\sqrt{a} \in \mathbb{F}_q\).

Proof. All the inequalities follow from Theorem 2, Lemma 4, and the Weil–Aubry–Perret inequality

\[
|\#C(\mathbb{F}_q) - (q + 1)| \leq 2p_\alpha(C)\sqrt{q} \quad [31, \text{Corollary 2.4}]
\]

for the number of \(\mathbb{F}_q\)-points on a projective (possibly singular) absolutely irreducible \(\mathbb{F}_q\)-curve \(C\). Let us apply these results below without further mentioning.

Obviously, \(\#h^{-1}(P_0) = 0\). Besides, according to the decompositions (4) we obtain

\[
\#C_{2,0}(\mathbb{F}_q) \leq 2(q + 1 + 6\sqrt{q}), \quad \#C_{\infty}(\mathbb{F}_q) \leq 4q + 1.
\]

We can not provide non-trivial lower bounds, because the components of \(C_{2,0}, C_{\infty}\) may be \(\mathbb{F}_q\)-conjugate. Therefore there is only the upper bound

\[
\#h^{-1}(\mathcal{O}) = \#(C_{\mathcal{O}} \setminus L)(\mathbb{F}_q) \leq \#C_{\mathcal{O}}(\mathbb{F}_q) \leq \#C_{2,0}(\mathbb{F}_q) + \#C_{\infty}(\mathbb{F}_q) \leq 6q + 12\sqrt{q} + 3.
\]

From now on, we focus on the case \(P = (x, y) = h(t_0, t_1) \not\in \{P_0, \mathcal{O}\}, \) where \(t_j \in \mathbb{F}_q^*\) as usual. Notice that \(x_j/t_j^2, y_j/t_j, t \in \mathbb{F}_q(t_0^4, t_1^4)\) and, in particular, \(f \in \mathbb{F}_q(t_0^4, t_1^4)\). We conclude that

\[
\varphi(it_0, t_1) = (-x_0, x_1, iy_0, y_1, t), \quad \varphi(t_0, it_1) = (x_0, -x_1, y_0, iy_1, t)
\]

and therefore

\[
[i](P) = \begin{cases} h(it_0, t_1) & \text{if } (\frac{1}{q})_4 = -i, \\ h(t_0, it_1) & \text{if } (\frac{1}{q})_4 = i. \end{cases}
\]

Also, in the case \(\sqrt{f} \in \mathbb{F}_q\) the weaker property

\[
\{[i]^j(P)\}_{j=0}^3 = h(\{(i^j)t_0, t_1\}_{j=0}^3)
\]
still holds by using the position number $m$ of $t_0$. Taking into account that $D_x, C_{\pm} \in \mathbb{F}_q[t_0^4, t_1^4]$, we eventually get
\[
\#h^{-1}(P) = \#h^{-1}(\mathbb{I}(P)) \quad \text{and so} \quad 4 \cdot \#h^{-1}(P) = \#(D_x \setminus L)(\mathbb{F}_q)
\]
if $P \not\in E_a[2]$ as well as
\[
\#h^{-1}(P_+) = \#h^{-1}(P_-) \quad \text{and so} \quad 2 \cdot \#h^{-1}(P_\pm) = \#(C_{\pm} \setminus L)(\mathbb{F}_q)
\]
if $\sqrt{a} \in \mathbb{F}_q$.
Equalities (2) result in the ones
\[
\deg(C_0 \cup C_1) = \deg(C_{2,\beta} \cup C_{2,-\beta}) = 16 \quad \text{and hence} \quad \deg(C_{\pm}) = 32.
\]
As a result, for
\[
N := \#C_0(\mathbb{F}_q) + \#C_1(\mathbb{F}_q) + \#C_{2,\beta}(\mathbb{F}_q) + \#C_{2,-\beta}(\mathbb{F}_q)
\]
it is true that
\[
N - 384 = N - 2 \cdot 8^2 - 16^2 \leq \#(C_0 \cup C_1)(\mathbb{F}_q) + \#(C_{2,\beta} \cup C_{2,-\beta})(\mathbb{F}_q) - 16^2 \leq \#C_{\pm}(\mathbb{F}_q).
\]
At the same time, by virtue of Equalities (3), (4) and Theorem 1 we obtain
\[
|\#C_{2,\beta}(\mathbb{F}_q) - (q + 1)| \leq 42\sqrt{q}, \quad \#C_{2,\pm\beta}(\mathbb{F}_q) \leq 4(q + 1).
\]
We can not provide a non-trivial lower bound for $\#C_{2,\pm\beta}(\mathbb{F}_q)$, because the conics $Q_{j,k,\pm}$ may be $\mathbb{F}_q$-conjugate. Thus
\[
2q - 84\sqrt{q} - 478 = 2(q + 1 - 42\sqrt{q}) - 384 - 3 \cdot 32 \leq
\]
\[
\#C_{\pm}(\mathbb{F}_q) - 3 \cdot 32 \leq \#(C_{\pm} \setminus L)(\mathbb{F}_q) \leq \#C_{\pm}(\mathbb{F}_q) \leq N \leq 10q + 84\sqrt{q} + 10.
\]
Eventually, we establish the desired inequalities
\[
q - 42\sqrt{q} - 239 \leq \#h^{-1}(P_\pm) \leq 5q + 42\sqrt{q} + 5.
\]
Equalities (2) result in the ones
\[
\deg(C_{x,1} \cup C_{\neg x,1}) = 16, \quad \deg(D_{0,x} \cup D_{1,x}) = 32, \quad \text{and hence} \quad \deg(D_x) = 48.
\]
As a result, for
\[
N_x := \#C_{x,1}(\mathbb{F}_q) + \#C_{\neg x,1}(\mathbb{F}_q) + \#D_{0,x}(\mathbb{F}_q) + \#D_{1,x}(\mathbb{F}_q)
\]
it is true that
\[
N_x - 832 = N_x - 8^2 - 16^2 - 16 \cdot 32 \leq \#(C_{x,1} \cup C_{\neg x,1})(\mathbb{F}_q) + \#(D_{0,x} \cup D_{1,x})(\mathbb{F}_q) - 16 \cdot 32 \leq \#D_x(\mathbb{F}_q).
\]
At the same time, by virtue of Equalities (3) and Theorem 1 we obtain
\[
|\#C_{2,x,\pm}(\mathbb{F}_q) - (q + 1)| \leq 42\sqrt{q}, \quad |\#D_{x,\pm}(\mathbb{F}_q) - (q + 1)| \leq 210\sqrt{q}.
\]
Thus
\[ 4q - 504\sqrt{q} - 972 = 4(q + 1) - 504\sqrt{q} - 832 - 3.48 \leq \]
\[ \#D_x(F_q) - 3.48 \leq \#(D_x \setminus L)(F_q) \leq \#D_x(F_q) \leq N_x \leq 4(q + 1) + 504\sqrt{q} \]
Eventually, we establish the inequalities
\[ |4 \cdot \#h^{-1}(P) - 4q| \leq 504\sqrt{q} + 972 \quad \text{and hence} \quad |\#h^{-1}(P) - q| \leq 126\sqrt{q} + 243. \]
The corollary is proved. \( \square \)

**Corollary 2.** The distribution on \( E_a(F_q) \) defined by \( h \) is \( \epsilon \)-statistically indistinguishable from the uniform one [9, Definition 3], where \( \epsilon := 2^7 q^{-1/2} + O(q^{-1}) \).

**Proof.** For any point \( P \in E_a(F_q) \) put
\[
\delta(P) := \left| \frac{\#h^{-1}(P)}{(q-1)^2} - \frac{1}{#E_a(F_q)} \right| \leq \gamma(P) + \left| \frac{1}{q-1} - \frac{1}{#E_a(F_q)} \right| = \gamma(P) + \frac{\#E_a(F_q) - (q-1)}{(q-1) \cdot #E_a(F_q)}
\]}
\[
\leq \gamma(P) + \frac{2(\sqrt{q} + 1)}{(q-1)(q-2\sqrt{q} + 1)} = \gamma(P) + \frac{2}{(\sqrt{q} - 1)(q - 2\sqrt{q} + 1)} = \gamma(P) + \frac{2}{q^{3/2}} + O\left(\frac{1}{q^2}\right),
\]
where
\[
\gamma(P) := \left| \frac{\#h^{-1}(P)}{(q-1)^2} - \frac{1}{q-1} \right| = \frac{|\#h^{-1}(P) - (q-1)|}{(q-1)^2}.
\]
If \( P \notin E_a[2] \) from Corollary 1 we immediately obtain
\[
\gamma(P) \leq \frac{126\sqrt{q} + 244}{(q-1)^2} \quad \text{and so} \quad \delta(P) = \frac{2^7 q^{-1/2} + O\left(\frac{1}{q^2}\right)}{q^{3/2}}.
\]
Besides, it is readily seen that \( \delta(P_0), \delta(P_\pm), \delta(\mathcal{O}) \in O(q^{-1}) \). Thus
\[
\sum_{P \in E_a(F_q)} \delta(P) \leq (q + 2\sqrt{q} + 1 - \#E_a(F_q)[2]) \left( \frac{2^7 q^{-1/2} + O\left(\frac{1}{q^2}\right)}{q^{3/2}} \right) + \sum_{P \in E_a(F_q)[2]} \delta(P) = \frac{2^7 q^{-1/2} + O\left(\frac{1}{q}\right)}{q^{1/2}}.
\]
The corollary is proved. \( \square \)

Probably, the coefficient \( 2^7 \) may be reduced even more by analysing singularities of the curves \( C_{2,v}, D_{j,x} \). For simplicity of the exposition, this analysis is omitted, because the value \( 2^7 q^{-1/2} \) is still negligible for \( q \) of a cryptographic size.

For \( t_1 \in F_q^* \) consider the encoding \( h_t : F_q^* \rightarrow E_a(F_q) \) of the form \( h_{t_1}(t_0) := h(t_0, t_1) \). Clearly, [9, Algorithm 1] still works well in the case of \( h \). Indeed, for \( P \in E_a(F_q) \) pick uniformly at random \( t_1 \in F_q^* \) and then find uniformly at random \( t_0 \in h_{t_1}^{-1}(P) \). For instance, when \( P \notin E_a[2] \), the latter consists in computing a non-zero \( F_q \)-root (if any) of one of the four polynomials \( C_{2,\pm v-1}, D_{j,\pm x} \in F_q[t_0] \) chosen randomly. We eventually obtain

**Remark 2.** The map \( h \) is samplable [9, Definition 4].

Remarks 1, 2 and Corollary 2 imply that \( h \) is an admissible map. Finally, using [9, Theorem 1], we establish
Corollary 3. Consider the composition \( H := h \circ h : \{0,1\}^* \rightarrow E_a(F_q) \) of a hash function \( h : \{0,1\}^* \rightarrow (F_q^*)^2 \) and \( h \). The hash function \( H \) is indifferentiable from a random oracle if \( h \) is so.

If in the given corollary one desires to use a random oracle of the form \( h : \{0,1\}^* \rightarrow F_q^2 \), the map \( h \) can be (manually) extended to \( F_q^2 \), e.g., as for \( h \) from [17, §2]. It is clear that such an extension does not affect the admissibility of our \( h \). On the other hand, it is not more difficult to construct a random oracle \( h : \{0,1\}^* \rightarrow (F_q^*)^2 \), acting by analogy with [9, Lemma 14 and Remark 1]. Indeed, the value of an indifferentiable hash function \( \{0,1\}^* \rightarrow F_q \) is equal to 0 with a negligible probability. Even so, it is suggested to return, e.g., 1. It follows easily that the indifferentiability still holds.

Acknowledgements. The author is grateful to Trepalin A. for answering some of his questions.
