**Abstract.** HMAC and NMAC are the most basic and important constructions to convert Merkle-Damgård hash functions into message authentication codes (MACs) or pseudorandom functions (PRFs). In the quantum setting, at CRYPTO 2017, Song and Yun showed that HMAC and NMAC are quantum pseudorandom functions (qPRFs) under the standard assumption that the underlying compression function is a qPRF. Their proof guarantees security up to  $O(2^{n/5})$  or  $O(2^{n/8})$  quantum queries when the output length of HMAC and NMAC is  $n$  bits. However, there is a gap between the provable security bound and a simple distinguishing attack that uses  $O(2^{n/3})$  quantum queries. This paper settles the problem of closing the gap. We show that the tight bound of the number of quantum queries to distinguish HMAC or NMAC from a random function is  $\Theta(2^{n/3})$  in the quantum random oracle model, where compression functions are modeled as quantum random oracles. To give the tight quantum bound, based on an alternative formalization of Zhandry’s compressed oracle technique, we introduce a new proof technique focusing on the symmetry of quantum query records.

**Keywords:** symmetric-key cryptography · post-quantum cryptography · provable security · quantum security · compressed oracle technique · HMAC · NMAC.

## 1 Introduction

In recent years, post-quantum cryptography is one of the most active research areas in cryptography. NIST is holding the standardization process for post-quantum *public-key* schemes such as public-key encryption, key-establishment algorithms, and signatures [27], and it is anticipated that currently used public-key schemes (such as RSA-based schemes) will be replaced with post-quantum ones in a near future. In the post-quantum era, it is desirable that we have some mathematical evidence that *symmetric-key* schemes also have post-quantum security. Studying post-quantum security of typical symmetric-key schemes is also an interesting problem from the view point of cryptographic theories, and there have been a significant number of recent papers that focus on this topic [31,20,18,14].

There exist two post-quantum security notions for cryptographic schemes: *standard security* and *quantum security* [32]. If a scheme  $\mathcal{S}$  is proven to be secure in the setting where adversaries have quantum computers but they make only *classical* queries to keyed oracles,  $\mathcal{S}$  is said to have *standard security*. If  $\mathcal{S}$  is proven to be secure even if adversaries are allowed to make quantum superposed queries to keyed oracles,  $\mathcal{S}$  is said to have *quantum security*. Quantum security is the ultimate security since, if  $\mathcal{S}$  has quantum security,  $\mathcal{S}$  satisfies arbitrary intermediate security notions between standard security and quantum security<sup>3</sup>.

Message authentication codes (MACs) are the most important symmetric-key schemes to achieve data integrity. Some of them including block cipher based MACs such as CBC-MAC [5,7,21] and PMAC [8] do not have quantum security, since there exist polynomial time attacks on them [22]. However, they have standard security since their classical security proofs remain valid if adversaries are allowed to make only classical queries to keyed oracles and the underlying block ciphers are post-quantum secure.

On the other hand, classical security proofs are not necessarily applicable to the (post-quantum) standard security for hash based MACs where the proofs use idealized models such as the random oracle model (when underlying hash functions are built on the Merkle-Damgård construction, e.g., SHA-2 [25]) or the ideal permutation model (when underlying hash functions are built on the sponge construction, e.g., SHA-3 [26]). Since adversaries can implement compression functions and permutations used in the hash functions on their own quantum computers to make quantum queries, the security of hash based MACs should be proven in the corresponding idealized quantum models such as the quantum random oracle model (QROM) [9] or quantum ideal permutation model [2,20].

The main focus of this paper is to study the tight quantum pseudorandom function security (qPRF security) of HMAC and its variant NMAC [4], which are the most basic and important constructions to convert Merkle-Damgård hash functions into pseudorandom functions (PRFs) or MACs, in the QROM where compression functions are modeled as quantum random oracles (QROs).

**HMAC and NMAC.** For a compression function  $h : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$ , the Merkle-Damgård construction  $\text{MD}^h$  is defined as follows<sup>4</sup>: Let  $IV \in \{0, 1\}^n$  be a fixed public initialization vector. For each input message  $M \in \{0, 1\}^*$ , the construction pads  $M$  (with a fixed padding function) and splits it into  $m$ -bit message blocks  $M[1], \dots, M[\ell]$ . The state is first set as  $S_0 := IV$ , and iteratively updated as  $S_{i+1} := h(M[i+1]||S_i)$ , and  $S_\ell$  becomes the final output. We assume  $m \geq n$ , which is the case for usual concrete hash functions such as SHA-2.

For a key length  $k \leq m$ , HMAC is defined to be the keyed function  $\text{HMAC}^h : \{0, 1\}^k \times \{0, 1\}^n \times \{0, 1\}^* \rightarrow \{0, 1\}^n$  such that  $\text{HMAC}^h(K, IV, M) := \text{MD}^h(IV,$

<sup>3</sup> Please do not confuse the notions of standard/quantum security with the standard model or the quantum random oracle model. The two notions are independent of the models, and it is possible that a scheme has quantum security in the standard model or standard security in the quantum random oracle model.

<sup>4</sup>  $n$  is the length of chaining values, and  $m$  is the length of message blocks.

$K_{out} || \text{MD}^h(IV, K_{in} || M)$ ). Here,  $K_{in} := (K || 0^{m-k}) \oplus \text{ipad}$ ,  $K_{out} := (K || 0^{m-k}) \oplus \text{opad}$ , and  $\text{ipad}, \text{opad} \in \{0, 1\}^m$  are fixed public constants such that  $\text{ipad} \neq \text{opad}$ . We sometimes write  $\text{HMAC}_K^h(IV, M)$  to denote  $\text{HMAC}^h(K, IV, M)$  for simplicity. See also Figure 1.

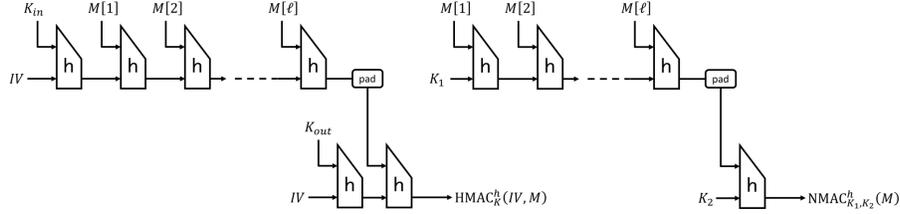

Fig. 1: HMAC and NMAC. Note that  $\text{pad}(M) = M[1] || \dots || M[\ell]$ .

NMAC is a two-key variant of HMAC. Mathematically, it is a keyed function  $\text{NMAC}^h : \{0, 1\}^n \times \{0, 1\}^n \times \{0, 1\}^* \rightarrow \{0, 1\}^n$  defined by  $\text{NMAC}^h(K_1, K_2, M) := \text{MD}^h(K_2, \text{MD}^h(K_1, M))$ . Here,  $K_1, K_2 \in \{0, 1\}^n$  are chosen independently and uniformly at random.<sup>5</sup> We sometimes write  $\text{NMAC}_{K_1, K_2}^h(M)$  instead of  $\text{NMAC}^h(K_1, K_2, M)$  for simplicity. See also Figure 1.

### Quantum security of HMAC and NMAC.

*Simple Quantum distinguishing attacks on HMAC and NMAC.* There are two simple quantum attacks to distinguish HMAC from a random function. Suppose that we are given an oracle  $\mathcal{O}$  that is either of HMAC or a random function, in addition to the quantum random oracle  $h$ .

The first attack is the one that tries to recover the secret key  $K$ . Once we succeed in recovering the correct key  $K$  (when  $\mathcal{O}$  is HMAC) or realizing that there is no plausible candidate for  $K$  (when  $\mathcal{O}$  a random function), we can distinguish HMAC from a random function. Since the exhaustive key search of  $k$ -bit keys can be done with  $O(2^{k/2})$  queries by using Grover's algorithm [17], we can distinguish HMAC from a random function with  $O(2^{k/2})$  quantum queries.

The second attack uses a collision for  $\mathcal{O}$ . Suppose that the padding function  $\text{pad}$  in the Merkle-Damgård construction satisfies the condition that there exists a function  $\mathbf{p} : \mathbb{Z}_{\geq 0} \rightarrow \{0, 1\}^*$  such that  $\text{pad}(M) = M || \mathbf{p}(|M|)$ , which is the case for usual hash functions such as SHA-2. First, we try to find  $M, M' \in \{0, 1\}^m$  such that  $\mathcal{O}(M) = \mathcal{O}(M')$ , which can be done with  $O(2^{n/3})$  quantum queries by using the BHT algorithm [11]. When we find such messages, we check whether  $\mathcal{O}(M || 0^m) = \mathcal{O}(M' || 0^m)$  holds. This equality holds with a high probability if  $\mathcal{O}$  is HMAC, but it holds with a negligible probability if  $\mathcal{O}$  is a random function.

<sup>5</sup> Note that there is no  $IV$  involved in NMAC and the key-length is always  $n + n = 2n$ .

Thus, we can distinguish HMAC from a random function with  $O(2^{n/3})$  quantum queries.

In summary, HMAC can be distinguished with  $O(\min\{2^{n/3}, 2^{k/2}\})$  quantum queries. The attacks are also applicable for NMAC, and  $O(\min\{2^{n/3}, 2^{2n/2}\}) = O(2^{n/3})$  is an upper bound of the query complexity to distinguish NMAC.

*Previous results on quantum security of HMAC and NMAC.* Song and Yun proved that HMAC and NMAC become secure quantum pseudorandom functions (qPRFs) against polynomial-time quantum adversaries in the *standard model* under the assumption that  $h(\cdot||K) : \{0, 1\}^m \rightarrow \{0, 1\}^n$  is a qPRF when  $K \in \{0, 1\}^n$  is randomly chosen [31]. They for the first time showed that HMAC and NMAC are secure even in the quantum setting, which has great importance in theory because it enables domain extension for qPRFs.

Roughly speaking, their proof guarantees security up to  $O(2^{n/5})$  or  $O(2^{n/8})$  quantum queries when the underlying function  $h_K$  is ideally random for each key  $K$ .<sup>6</sup> In other words,  $\Omega(2^{n/5})$  or  $\Omega(2^{n/8})$  is currently the best proven lower bound of quantum query complexity to distinguish HMAC or NMAC from a random function.

Results in standard models and those in (quantum) random oracles are not directly comparable, but there exists a large gap between the current best lower bound and the upper bound  $O(2^{n/3})$  (when  $k$  is large enough) given in the above distinguishing attacks.

The gap between  $\Omega(2^{n/5})$  (or  $\Omega(2^{n/8})$ ) and  $O(2^{n/3})$  may not be significant in an ideal world where adversaries are modeled as polynomial-time machines, but it is indeed significant in the real world applications, which we explain below.

*Closing the gap.* In the real world, closing the gap between  $\Omega(2^{n/5})$  (or  $\Omega(2^{n/8})$ ) and  $O(2^{n/3})$  is relevant for the following reasons.

Recall that there exist two security notions in the quantum setting: quantum security and standard security. The standard security of HMAC will have practical importance in a very near future because it is quite reasonable to assume that an adversary has a quantum computer on which  $h$  is implemented, but the attack target (HMAC) is implemented on a classical device.

Now, the problem is that existing results guarantee the security of HMAC and NMAC only up to  $O(2^{n/5})$  or  $O(2^{n/8})$  queries, not only for the quantum security but also for the standard security (in the QROM). This is problematic since when HMAC is instantiated with SHA-256, where  $n = 256$ , the security is not guaranteed after about  $2^{n/5} \approx 2^{52}$  (or  $2^{n/8} \approx 2^{32}$ ) *classical* queries. It is completely unacceptable in practice, as the number is modest even with the current standard, and is too small to guarantee a longer term security.

In theory, the security up to  $O(2^{n/3})$  queries can be guaranteed with the previous result if the security parameter is changed from  $n$  to  $5n/3$  (or  $8n/3$ ),

<sup>6</sup> Actually, the previous work [31] did not give concrete security bound, but we can reasonably deduce that the security is guaranteed up to  $O(2^{n/8})$  quantum queries. We have the bound  $O(2^{n/5})$  instead of  $O(2^{n/8})$  if we assume a conjecture. See Section A in the appendix for details.

by replacing the underlying hash function with the one with a longer output length. However, in the real world, it requires many years to change parameters or primitives of widely used symmetric-key cryptosystems such as HMAC, or sometimes it is simply infeasible, as we illustrate below:

- Some small IoT devices (e.g., RFID tags) need MACs but do not have enough area for hardware implementation of primitives with large parameters.
- Some banking systems are still using Triple-DES although 20 years have already passed after the standardization of AES [3]. This is because even a small change (changing the block cipher) in financial systems is too costly.
- Artificial satellites require MACs to prevent accepting commands from malicious attackers. Changing primitives embedded as hardware is infeasible after satellites are launched into the outer space [30].

Hence, giving a precise security bound is relevant from a practical view point, and is one of the most important topics to study in symmetric-key cryptography, even if the improvement will be from  $O(2^{n/5})$  (or  $O(2^{n/8})$ ) to  $O(2^{n/3})$ .

We also note that there has been a long line of research to close the gap for HMAC and NMAC in the classical setting, and it was eventually addressed by Gazi et al. at CRYPTO 2014 [16] showing the upper bound and the matching lower bound. However, the analysis in the quantum setting does not reach this point, and closing the gap is important also from a theoretical view point.

## 1.1 Our Contributions

The main result of this paper is the following theorem, which shows that the tight bound of the number of quantum queries to distinguish HMAC or NMAC from a random function is in  $\Theta(2^{n/3})$  (when  $k$  is large enough).

**Theorem 1 (Lower bound, informal).** *Assume  $m \geq n$ . Suppose that the maximum length of messages that we can query to HMAC, NMAC, or a random function RF (which is independent of  $h$ ) is at most  $m \cdot \ell$ . Then, the following claims hold in the model where  $h$  is a quantum random oracle.*

1. *To distinguish HMAC from RF with a constant probability by making at most  $Q$  queries to HMAC or RF and at most  $q_h$  queries to  $h$ ,  $q_h \cdot \ell^{5/3} + Q \cdot \ell^{5/3} \geq \Omega(2^{n/3})$ , or  $q_h + Q \cdot \ell \geq \Omega(2^{k/2})$  have to be satisfied.*
2. *To distinguish NMAC from RF with a constant probability by making at most  $Q$  queries to NMAC or RF and at most  $q_h$  queries to  $h$ ,  $q_h \cdot \ell^{5/3} + Q \cdot \ell^{5/3} \geq \Omega(2^{n/3})$  has to be satisfied.*

*Remark 1.* Our tightness claim focuses on the number of quantum queries, neglecting the effect of the lengths of the queries (see also Figure 2). Nevertheless, our result still has practical importance. For instance, when HMAC-SHA-256 is used to authenticate TCP/IP packets on Ethernet,  $\ell < 32$  always holds since Maximum Segment Size (MSS) is about 1500-byte. In such a use-case our result guarantees about 85-bit security ( $2^{n/3} \approx 2^{85}$  for  $n = 256$ ), while previous works do only about 52-bit security or 32-bit security (in the QROM).

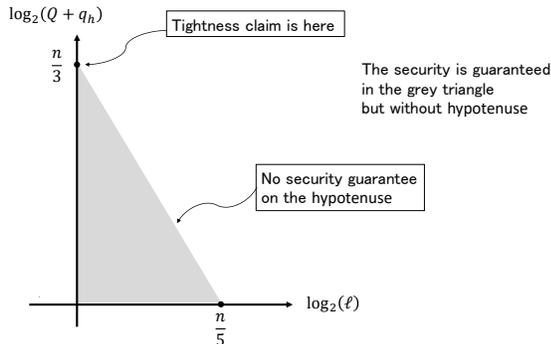

Fig. 2: The area that our result guarantees security (the grey triangle). We claim tightness of the bound for  $\ell = O(1)$ .

*Remark 2.* Some readers may think that results in the standard model are always superior to those in the (Q)ROM, but we emphasize that the standard model and (Q)ROM are theoretically incomparable.

To show the theorem, we use an alternative formalization [18,19] of Zhandry’s *compressed oracle technique* [33]. One of the most difficult issues in proving security of cryptographic schemes against quantum adversaries is to record quantum queries to oracles. Zhandry [33] solved the issue by developing the compressed oracle technique, which can be used to record queries to QROs and efficiently simulate QROs. Intuitively, by using the technique, we can use the classical *lazy sampling* for quantum random oracles to some extent. The technique is so powerful that it is used to prove security of many cryptographic schemes [18,33,23,12,24,6]. However, efficient simulations of QROs are not necessary when we focus on the number of quantum queries made by adversaries and when their running time is irrelevant. Based on this observation, Hosoyama and Iwata developed an alternative formalization of the compressed oracle technique that achieved a simpler formalization by ignoring efficient simulations of QROs and introducing notions of error terms, which is named *recording standard oracle with errors (RstOE)* [18,19]. Since our main focus is information theoretic adversaries of which computational resources are unlimited except for the number of quantum queries, we use RstOE instead of the original technique.

The technically hardest part to prove Theorem 1 is to show the indistinguishability of the function  $F_1^h(u, v) := h(v, f(u))$  from a random function, where  $u \in \{0, 1\}^n$ ,  $v \in \{0, 1\}^m$ , and  $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  is a random function that is independent of  $h$ . (Adversaries have a direct oracle access to the quantum random oracle  $h$ , but only indirect access to  $f$ . That is, adversaries can query to  $f$  only through queries to  $F_1^h$ , and cannot observe the output values of  $f$ . See also Figure 3.) Once we show the indistinguishability of  $F_1^h$ , the remaining proofs can be done with simpler proof techniques.

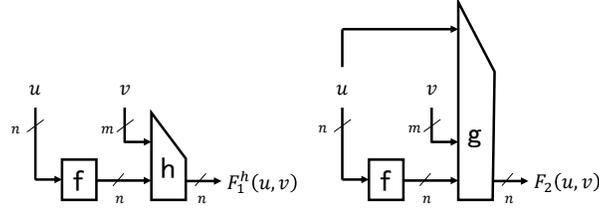

Fig. 3:  $F_1^h$  and  $F_2$ .  $h$  is a quantum random oracle that adversaries can directly access.  $f$  and  $g$  are random functions that are independent from  $h$ .

It turns out that previous techniques cannot be directly used to prove the indistinguishability of  $F_1^h$ . Thus we introduce a technique which we call *equivalent databases*. We explain the details in the next subsection.

## 1.2 Technical Overview

Let us denote the distinguishing advantage of an adversary  $\mathcal{A}$  between (pair of) oracles  $(\mathcal{O}_1^h, h)$  and  $(\mathcal{O}_2, h)$  by  $\mathbf{Adv}_{(\mathcal{O}_1^h, h), (\mathcal{O}_2, h)}^{\text{dist}}(\mathcal{A})$ , where  $h$  is a quantum random oracle and  $\mathcal{O}_1^h$  depends on  $h$ . Let RF be a random function that is independent of  $h$ . As mentioned above, the technically hardest part to show the tight security bound of HMAC and NMAC is to show the following proposition<sup>7</sup>.

**Proposition 1 (Technically hardest proposition to show, informal).** *If  $\mathcal{A}$  makes at most  $q$  queries to each oracle,  $\mathbf{Adv}_{(F_1^h, h), (\text{RF}, h)}^{\text{dist}} \leq O(\sqrt{q^3/2^n})$  holds.*

Let  $F_2$  be the function defined by  $F_2(u, v) := g(u, v, f(u))$ , where  $g : \{0, 1\}^n \times \{0, 1\}^m \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  is another random function (see also Figure 3). Then, since  $g$  is a random function,  $\mathbf{Adv}_{(F_1^h, h), (\text{RF}, h)}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A})$  holds. In what follows, we present an overview of how we show

$$\mathbf{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq O(\sqrt{q^3/2^n}), \quad (1)$$

instead of directly showing Proposition 1. For bit strings  $x$  and  $y$ , we identify the concatenation  $x||y$  and the pair  $(x, y)$ .<sup>8</sup>

Following usual terminology on provable security in symmetric-key cryptography, we call (direct) queries to  $h$  *offline queries* because  $h$  is an ideal model of a public function that adversaries can compute offline. In addition, we call queries to  $F_1^h$  and  $F_2$  *online queries* because the oracles of  $F_1^h$  and  $F_2$  model the keyed functions that adversaries can compute only by making online queries.

<sup>7</sup> In [33] Zhandry showed that  $F_1^h$  is indifferentiable from a QRO when  $h$  and  $g$  are QROs. His result implies qPRF security of  $F_1^h$  up to  $O(2^{n/4})$  quantum queries, while Proposition 1 guarantees security up to  $O(2^{n/3})$  queries.

<sup>8</sup> We consider  $F_2$  instead of RF so that there exists a useful correspondence between “good” databases for  $F_1^h$  and those for  $F_2$ , which we will elaborate later.

**Classical proof intuitions.** If our goal were to show the indistinguishability of  $F_1^h$  and  $F_2$  in the *classical* setting, we could show it based on the following idea by using the *lazy sampling* technique to  $f$ ,  $g$ , and  $h$ :

*If  $\mathcal{A}$  cannot guess outputs of  $f$ , and outputs of  $f$  do not collide, then the outputs of  $F_1^h$  and  $F_2$  seem completely random and indistinguishable.*

More precisely, a (classical) adversary  $\mathcal{A}$  cannot distinguish  $F_1^h$  and  $F_2$  as long as the following two bad events *hit* and *coll* do not happen.<sup>9</sup>

- hit*:  $\mathcal{A}$  succeeds in guessing a previous output of  $f$  and queries it to  $h$ . That is,  $\mathcal{A}$  has queried  $u||v'$  to the online keyed oracle ( $F_1^h$  or  $F_2$ ) before, and now  $\mathcal{A}$  queries  $v||f(u)$  to  $h$  (for some  $v \in \{0, 1\}^m$ ).
- coll*: A new output of  $f$  (which is sampled during an online query) happens to collide with either of (a) a previous output of  $f$ , or (b) the least significant  $n$ -bit  $\zeta$  of a previous offline query  $v||\zeta$  to  $h$ .

Our proof for the *classical* indistinguishability would be as follows: First, we show that  $F_1^h$  and  $F_2$  are completely indistinguishable as long as *hit* and *coll* do not happen. Second, we show that  $\Pr[\text{hit}]$  and  $\Pr[\text{coll}]$  are small. Let  $\text{coll}_i$  denote the event that *coll* happens at the  $i$ -th query. Then, by using the randomness of outputs of  $f$ , we can show  $\Pr[\text{coll}_i] \leq O(i/2^n)$  for each  $i$ , which implies that  $\Pr[\text{coll}] \leq \sum_{1 \leq i \leq q} \Pr[\text{coll}_i] \leq \sum_{1 \leq i \leq q} O(i/2^n) = O(q^2/2^n)$ . Similarly,  $\Pr[\text{hit}] \leq O(q^2/2^n)$  can be shown. (Actually there exists a qualitative difference between the proof for  $\Pr[\text{coll}] \leq O(q^2/2^n)$  and that for  $\Pr[\text{hit}] \leq O(q^2/2^n)$ , which will be explained later). Hence we can show  $\mathbf{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq \Pr[\text{coll}] + \Pr[\text{hit}] \leq O(q^2/2^n)$  in the classical setting.

**How to show quantum indistinguishability?** When we show the *quantum* indistinguishability of  $F_1^h$  and  $F_2$ , it is natural to combine the above *classical* idea with some quantum proof techniques developed in previous works. Indeed, our first idea toward a quantum proof is to combine the above classical idea with a quantum technique introduced in [18,19].<sup>10</sup> However, actually it turns out that they cannot be simply combined. The issue is attributed to our situation where we have to deal with the bad event *hit* that “ $\mathcal{A}$ ’s *offline* query to  $h$  collides with a previous output of  $f$  in the *online* oracle”.

Below, we explain (1) an overview of the previous quantum proof technique, (2) what kind of issue arises if we combine the above classical idea with the previous quantum technique, and that (3) we can solve the issue by introducing a new proof technique which we name *equivalent databases*.

<sup>9</sup> We use the symbols  $u$  and  $\zeta$  to denote  $n$ -bit strings and  $v$  to denote an  $m$ -bit string.  
<sup>10</sup> In Zhandry’s paper that introduced the compressed oracle technique, quantum indifferentiability of the *fixed-input-length* Merkle-Damgård construction is proved [33]. Note that the *variable-input-length* Merkle-Damgård construction that is used in HMAC and NMAC is not indifferentiable in the random oracle model even in the classical setting [13]. In addition, the security bound of the indifferentiability is proved up to  $O(2^{n/4})$  (but not  $O(2^{n/3})$ ) quantum queries in [33]. Thus, we start from the proof technique used in [18,19] instead of [33].

**Proof technique in [18,19].** The previous work [18,19] showed quantum indistinguishability (Proposition 4 in [19]) of certain two oracles as follows: <sup>11</sup>

1. Suppose that random functions from which the oracles are built (in our case,  $f$ ,  $g$ , and  $h$ ) are implemented by using RstOE so that we can use intuitions of classical lazy sampling in quantum proofs to some extent (let  $D_f$ ,  $D_g$ , and  $D_h$  denote *databases* associated with RstOE for  $f$ ,  $g$ , and  $h$ , respectively, which correspond to transcripts of queries in the classical setting).
2. Based on classical proof ideas of using good and bad events, define the notion of *good* and *bad* for tuples of databases (in our case,  $(D_f, D_h)$  for  $F_1^h$  and  $(D_f, D_g, D_h)$  for  $F_2$ ) in such a way that
  - (a) There exists a one-to-one correspondence between good databases for one oracle (in our case, good databases  $(D_f, D_h)$  for  $F_1^h$ ) and good databases for the other oracle (in our case, good databases  $(D_f, D_g, D_h)$  for  $F_2$ ).
  - (b) The behavior of one oracle (in our case,  $F_1^h$ ) on a good database is the same as that of the other oracle (in our case,  $F_2$ ) on the corresponding good database.
3. By using (a) and (b), show that the oracles (in our case, the pairs of the oracles  $(F_1^h, h)$  and  $(F_2, h)$ ) are completely indistinguishable as long as databases are good.
4. Show that the probability (in some sense) that good databases change to bad databases is very small at each query.

Note that, unlike the setting, even if the record “ $x$  has been queried to  $f$  and responded with  $y$ ” is stored in a database  $D_f$  for  $f$ , there is a possibility that the record will be overwritten as “ $x$  has not been queried to  $f$  before”, or “ $x$  has been queried to  $f$  and responded with  $y'$ ” for some  $y' \neq y$  <sup>12</sup>. Hence it is not necessarily trivial how to define good and bad databases in such a way that we can formally prove both of (a) and (b) hold.

Next, we explain what kind of issue happens when we apply the above idea to our situation. In short, the issue lies in the last one of the above four steps.

**An issue with our situation.** In the previous work [18,19], each adversary can access to only a single *keyed* oracle. Roughly speaking, a good database changes to bad only when a fresh value  $x$  is (indirectly) queried to a random function RF, and the newly sampled value  $y := \text{RF}(x)$  happens to collide with an existing record in a database (i.e., a bad event that correspond to *coll* in our situation).

<sup>11</sup> Some technical errors are contained in the Asiacrypt version of the previous work [18], which are corrected in the revised version [19]. Our technical overview in this section and formal proofs in later sections are based on the revised version. For completeness, we do not rely on any propositions in [18,19] that is related to the technical errors in [18]. The propositions from [18,19] that we use in this paper are the ones of which correctness can be confirmed just by straightforward algebraic calculation (Proposition 2 and Proposition 3).

<sup>12</sup> This may seem somewhat strange, but some differences between quantum oracles and classical oracles are explained by using this strange property.

On the other hand, in our situation, a good database also changes to bad when an adversary succeeds to query  $v||\zeta$  to  $h$  such that  $\zeta$  collides with a previous output of  $f$  (i.e., hit occurs).

This difference causes an issue to prove that the “bad” probability is small. Unlike the lazy sampling that always chooses values uniformly at random, (quantum) adversaries can choose offline (quantum) queries to  $h$  arbitrarily and *adaptively*. Thus, an adversary may have strong ability to succeed to cause hit, even if the probability of coll is small.

Note that how to deal with adaptive queries to offline queries is not an easy issue even in the classical setting. To reduce the arguments on adaptive queries into those on non-adaptive arguments, sophisticated proof techniques such as the coefficients H technique [28] are usually used.

**How to solve the issue.** Our key intuition to solve the issue is, for arbitrary good database  $(D_f, D_h)$  for  $F_1^h$  that an adversary  $\mathcal{A}$  is trying to change to be bad, there would be sufficiently many good databases  $(D'_f, D'_h)$  that  $\mathcal{A}$  cannot distinguish from  $(D_f, D_h)$ .

Suppose that (I)  $\mathcal{A}$  is running relative to  $F_1^h$  and  $h$ , and has made  $(i - 1)$  queries in total, (II) both of the bad events coll and hit have not happened, and (III) now  $\mathcal{A}$  chooses a bit string  $\tilde{v}||\tilde{\zeta}$  to query to  $h$ , trying to cause hit at the  $i$ -th query.

Let  $D_f$  and  $D_h$  be the current databases for  $f$  and  $h$  (before the  $i$ -th query). Then there exist  $u_1, \dots, u_s, \alpha_1, \dots, \alpha_s \in \{0, 1\}^n$  ( $s \leq i - 1$ ) such that  $D_f = ((u_1, \alpha_1), \dots, (u_s, \alpha_s))$ . Intuitively,  $\alpha_j$  is equal to  $f(u_j)$ . Since bad events have not happened yet,  $D_f$  does not contain any collision (i.e.,  $\alpha_i \neq \alpha_j$  for  $i \neq j$ ).

Let  $\text{hit}_i$  denote the event that hit occurs at the  $i$ -th query (to  $h$ ). Then,  $\text{hit}_i$  occurs when  $\mathcal{A}$  successfully chooses a value  $\tilde{v}||\tilde{\zeta}$  such that  $\tilde{\zeta} = \alpha_j$  holds for some  $j$ . Our current goal is to prove that  $\Pr[\text{hit}_i]$  is very small.

To achieve this goal, we show that  $\Pr[\text{hit}_i | \mathcal{A} \text{ chooses } \tilde{v}||\tilde{\zeta}]$  is very small for arbitrary  $\tilde{v}||\tilde{\zeta}$ , by focusing on the freedom of the choices of the values  $f(u_1) = \alpha_1, \dots, f(u_s) = \alpha_s$ . Intuitively, even if the value  $\alpha_j (= f(u_j))$  in the element  $(u_j, \alpha_j) \in D_f$  is replaced with another value  $\alpha'_j$ ,  $\mathcal{A}$  does not notice since  $\mathcal{A}$  does not observe output values of  $f$ . This means that the choices of the values  $f(u_1) = \alpha_1, \dots, f(u_s) = \alpha_s$  have some degree of freedom, even after  $\mathcal{A}$  has chosen which value  $\tilde{v}||\tilde{\zeta}$  to query to  $h$ . We use this degree of freedom to bound the probability  $\Pr[\text{hit}_i | \mathcal{A} \text{ chooses } \tilde{v}||\tilde{\zeta}]$  (actually we will show a stronger result).

To provide a proof based on the above intuition, we introduce the notion of *equivalent databases* as follows.

**Definition 1 (Equivalent database, informal).** A (good) database  $(D'_f, D'_h)$  is said to be equivalent to  $(D_f, D_h)$  if  $|D'_f| = |D_f|$ ,  $|D'_h| = |D_h|$ , and  $(D'_f, D'_h)$  is equal to  $(D_f, D_h)$  except for the choices of the output values of  $f$ .

We present an example to illustrate the intuition on equivalent databases. Let  $D_f := ((u_1, \alpha_1), (u_2, \alpha_2))$  and  $D_h := ((v_1||\alpha_1, w_1), (v_2^{(1)}||\alpha_2, w_2^{(1)}), (v_2^{(2)}||\alpha_2, w_2^{(2)}))$ ,

$(v_3||\zeta_3, w_3)$ ). This corresponds to the situation where  $u_1||v_1$ ,  $u_2||v_2^{(1)}$ ,  $u_2||v_2^{(2)}$  have been queried to  $F_1^h$ , and  $v_3||\zeta_3$  has been queried to  $h$ . See also Figure 4. The adversary observes that  $F_1^h(u_1||v_1) = w_1$ ,  $F_1^h(u_2||v_2^{(1)}) = w_2^{(1)}$ ,  $F_1^h(u_2||v_2^{(2)}) = w_2^{(2)}$ , and  $h(v_3||\zeta_3) = w_3$ , but does not know the values  $\alpha_1 = f(u_1)$  and  $\alpha_2 = f(u_2)$ . Suppose  $\alpha_1, \alpha_2, \zeta_3$  are distinct, which implies that  $(D_f, D_h)$  is a good database. Then, another good database  $(D'_f, D'_h)$  is equivalent to  $(D_f, D_h)$  if and only if there exist  $\alpha'_1$  and  $\alpha'_2$  such that  $\alpha'_1, \alpha'_2, \zeta_3$  are distinct,  $D'_f = ((u_1, \alpha'_1), (u_2, \alpha'_2))$ , and  $D'_h = ((v_1||\alpha'_1, w_1), (v_2^{(1)}||\alpha'_2, w_2^{(1)}), (v_2^{(2)}||\alpha'_2, w_2^{(2)}), (v_3||\zeta_3, w_3))$ .

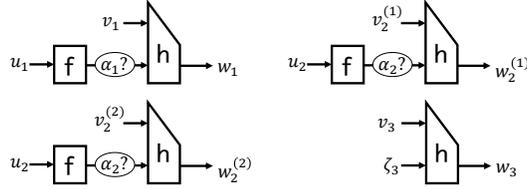

Fig. 4: The situation that corresponds to the good database  $(D_f, D_h)$ .  $\mathcal{A}$  has no information on  $\alpha_1$  and  $\alpha_2$  except that  $\alpha_1, \alpha_2, \zeta_3$  are distinct. We say that another good database  $(D'_f, D'_h)$  is equivalent to  $(D_f, D_h)$  if and only if  $(D_f, D_h)$  is equal to  $(D'_f, D'_h)$  except for the choice of the values for  $\alpha_1$  and  $\alpha_2$ .

Let  $\text{Equiv}(D_f, D_h)$  be the set of good databases that are equivalent to  $(D_f, D_h)$ . Then, intuitively, the following properties hold:

1. The probability that a database happens to become  $(D_f, D_h)$  (after  $\mathcal{A}$  made  $(i-1)$  queries) is equal to the probability that the database happens to become  $(D'_f, D'_h)$ , for any  $(D'_f, D'_h) \in \text{Equiv}(D_f, D_h)$ .
2. The ratio between (I) the number of  $(D'_f, D'_h) \in \text{Equiv}(D_f, D_h)$  that leads to the bad event  $\text{hit}_i$  (i.e.,  $\alpha_j = \tilde{\zeta}$  for some  $j$ ) and (II) the size of the entire set  $\text{Equiv}(D_f, D_h)$  is at most about  $\approx |D_f|/2^n \leq O(i/2^n)$ .<sup>13</sup>

From the above two properties it follows that, for arbitrary  $\tilde{v}||\tilde{\zeta}$  and arbitrary good  $(D_f, D_h)$ ,  $\Pr[\text{hit}_i | \mathcal{A} \text{ chooses } \tilde{v}||\tilde{\zeta} \wedge \text{database is equivalent to } (D_f, D_h)] \leq O(i/2^n)$  holds. This implies that  $\Pr[\text{hit}_i] \leq O(i/2^n)$ .

The above explanations are in fact based on classical intuitions. To show they also work in the quantum setting, we carefully analyze quantum amplitude (complex coefficients) of state vectors.

<sup>13</sup> This holds due to the following reasoning. For simplicity, assume that nothing has been *directly* queried to  $h$  before, and  $D_f$  has  $(i-1)$  entries  $(u_1, \alpha_1), \dots, (u_{i-1}, \alpha_{i-1})$  (other cases can be shown similarly). Then  $|\text{Equiv}(D_f, D_h)|$  is equal to the number of choices of the tuple  $(\alpha_1, \dots, \alpha_{i-1})$  such that  $\alpha_j \neq \alpha_k$  for  $j \neq k$ . Hence  $|\text{Equiv}(D_f, D_h)| = \binom{2^n}{i-1}$ . In addition, the number of  $(D'_f, D'_h) \in \text{Equiv}(D_f, D_h)$  such that  $\alpha_j = \tilde{\zeta}$  for some  $j$  is  $(i-1) \cdot \binom{2^n}{i-2}$ . Thus the ratio is  $(i-1) \cdot \binom{2^n}{i-2} / \binom{2^n}{i-1} = \frac{(i-1)}{(2^n - i + 2)} \leq O(i/2^n)$ .

**Finishing the proof.** Now we have  $\Pr[\text{hit}_i] \leq O(\frac{i}{2^n})$  in the quantum setting. We can also show  $\Pr[\text{coll}_i] \leq O(\frac{i}{2^n})$  with the technique in the previous work [18].

In the classical setting, the distinguishing advantage is upper bounded by  $\text{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq \Pr[\text{hit}] + \Pr[\text{coll}] \leq \sum_{1 \leq i \leq q} \Pr[\text{hit}_i] + \sum_{1 \leq i \leq q} \Pr[\text{coll}_i]$ . On the other hand, roughly speaking, the quantum distinguishing advantage is upper bounded by  $\text{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq \sum_{1 \leq i \leq q} \sqrt{\Pr[\text{hit}_i]} + \sum_{1 \leq i \leq q} \sqrt{\Pr[\text{coll}_i]}$ . Therefore, we obtain the bound as  $\text{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq \sum_{1 \leq i \leq q} O\left(\sqrt{i/2^n}\right) + \sum_{1 \leq i \leq q} O\left(\sqrt{i/2^n}\right) \leq O\left(\sqrt{q^3/2^n}\right)$  in the quantum setting, instead of the classical bound  $O(q^2/2^n)$ .

The intuition behind the notion of equivalent databases might seem simple or even trivial, though, the important point is that we can provide a rigorous proof that the intuition actually works in the quantum setting through RstOE. (Recall that it was unclear how to record quantum queries before the development of the compressed oracle technique.)

As we mentioned before, it is quite important to show the tight security bound in symmetric cryptology because even the improvement from  $O(2^{n/5})$  (or  $O(2^{n/8})$ ) to  $O(2^{n/3})$  has significant importance in the real world. Bad events like hit that an adversary succeeds to guess an output of a random function often appear in classical provable security for symmetric-key cryptosystems. To deal with such bad events when showing quantum tight security bounds, proof techniques like our equivalent databases seem indispensable. We believe that our technique broadens the applicability of quantum provable security in symmetric-key cryptology.

### 1.3 Limitations and Future Directions

Our security bound is tight and any further improvement is impossible in terms of the number of queries. However, there is a room for improvement in terms of the length of messages. When an adversary makes a single classical query of very long length (e.g., a message of  $m \cdot 2^{n/5}$  bits, or equivalently  $\ell = 2^{n/5}$ ) to the keyed oracle of HMAC or NMAC, our result no longer guarantees any security. (Note that this does not invalidate the practical importance of our result. See Remark 1 for details.) However, we do not find any quantum attack that actually breaks the security of HMAC or NMAC by making only a few queries of which length is  $O(m \cdot 2^{n/5})$ , and we expect that there does not exist such an attack. Improving the security bound in terms of message lengths is an interesting future work.

### 1.4 Related Works

There are various notions on quantum MAC security such as EUF-qCMA security [10] and blind unforgeability [1]. There also exists another security notion for one-time MAC security [15]. MACs built from qPRFs satisfy all these

security notions. Boneh and Zhandry showed that qPRFs become quantum secure MACs (in the sense of EUF-qCMA) and showed quantum security of the Carter-Wegman MACs [10]. Czajkowski et al. showed quantum security of random sponge, which can be seen as a variant of CBC-MAC [14].

## 1.5 Paper Organization

Section 2 describes notation, definitions, and some basic lemmas used in later sections. Section 3 gives an overview on the alternative formalization (RstOE) of Zhandry’s compressed oracle technique. Section 4 gives the formal proof of the technically most hardest proposition (Proposition 1) and introduces the new proof technique. Section 5 shows quantum security bound of HMAC and NMAC.

## 2 Preliminaries

In this paper, all adversaries are quantum algorithms.  $I_n$  denotes the identity operator on  $n$ -qubit quantum states. We often write just  $I$  instead of  $I_n$  when it will cause no confusion. For a unitary operator  $U$ , we denote the operators  $U \otimes I$  and  $I \otimes U$  by the same symbol  $U$ , when it will cause no confusion. We identify the set of bit strings  $\{0, 1\}^n$  with the set of integers  $\{0, 1, \dots, 2^n - 1\}$  for any positive integer  $n$ . In addition, we identify the pair  $(x, y) \in \{0, 1\}^m \times \{0, 1\}^n$  with the concatenation  $x||y \in \{0, 1\}^{m+n}$ .  $\{0, 1\}^*$  denotes the set  $\coprod_{n=0}^{\infty} \{0, 1\}^n$ , where  $\{0, 1\}^0$  denotes the set that includes only the empty string. For a positive integer  $m$ ,  $(\{0, 1\}^m)^+$  denotes the set  $\coprod_{i=1}^{\infty} \{0, 1\}^{im}$ .  $\text{td}(\cdot, \cdot)$  denotes the trace distance function. For a vector  $|\phi\rangle$  and a positive integer  $n$ , we also denote  $|\phi\rangle \otimes |0^n\rangle$  and  $|0^n\rangle \otimes |\phi\rangle$  by  $|\phi\rangle$ , when it will cause no confusion.

### 2.1 Quantum Algorithms and Quantum Oracles

When we consider the computational resources of adversaries, we focus on the number of queries made by adversaries, and we do not care about their running time and memory usage (i.e., we consider quantum information theoretic adversaries). Here we describe how we model (oracle-aided) quantum algorithms and quantum oracles in the case that each adversary is given an oracle access to a single quantum oracle.

Following previous works (e.g., [9]), we model an (oracle-aided) quantum algorithm  $\mathcal{A}$  that makes at most  $q$  quantum queries to a single oracle as a sequence of unitary operators  $(U_0, U_1, \dots, U_q)$ , where  $U_i$  corresponds to  $\mathcal{A}$ ’s offline computation after the  $i$ -th oracle query for  $i \geq 1$ , and  $U_0$  corresponds to  $\mathcal{A}$ ’s initial computation. In addition, the quantum state space of  $\mathcal{A}$  is a tensor product  $\mathcal{H}_{\text{query}} \otimes \mathcal{H}_{\text{answer}} \otimes \mathcal{H}_{\text{work}}$ , where  $\mathcal{H}_{\text{query}}$ ,  $\mathcal{H}_{\text{answer}}$ , and  $\mathcal{H}_{\text{work}}$  correspond to the register to make queries to the oracle, the register to receive answers from the oracle, and the register for  $\mathcal{A}$ ’s offline computations, respectively. After the application of the final unitary operator  $U_q$ ,  $\mathcal{A}$ ’s entire state is measured, and (a part of) the measurement result (classical bit string) is returned as the output.

When  $\mathcal{A}$  does not take any initial input, we assume that  $\mathcal{A}$ 's initial state is set to be  $|0^s\rangle$  for some positive integer  $s$ . When  $\mathcal{A}$  takes a classical input  $x \in \{0, 1\}^m$ , we assume that  $\mathcal{A}$ 's initial state is set to be  $|x\rangle$  by convention. (This paper does not treat the situation that  $\mathcal{A}$  takes quantum states as inputs.)

A quantum oracle  $\mathcal{O}$  is modeled as a tuple of unitary operator  $O$ , quantum state space  $\mathcal{H}_{\text{query}} \otimes \mathcal{H}_{\text{answer}} \otimes \mathcal{H}_{\text{state}}$ , and a vector (initial state)  $|\text{init}\rangle \in \mathcal{H}_{\text{state}}$ . Here, the state space  $\mathcal{H}_{\text{query}} \otimes \mathcal{H}_{\text{answer}}$  (i.e., the registers to send queries and receive answers) is shared with adversaries, and  $\mathcal{H}_{\text{state}}$  is the oracle's private space that adversaries cannot access directly.  $O$  may be chosen randomly according to a distribution at the beginning of each game.

When the adversary  $\mathcal{A}$  runs relative to the quantum oracle  $\mathcal{O}$  on input  $x$ , the initial whole quantum state is  $|x\rangle \otimes |\text{init}\rangle$ . The whole quantum state just before the  $i$ -th query is  $U_{i-1}OU_{i-2}O \cdots OU_0|x\rangle \otimes |\text{init}\rangle$ , and the whole quantum state just before the final measurement is  $U_qOU_{q-1}O \cdots OU_0|x\rangle \otimes |\text{init}\rangle$ . Let  $z \leftarrow \mathcal{A}^{\mathcal{O}}(x)$  denote the event that the quantum algorithm  $\mathcal{A}$  returns  $z$  as the final output when  $\mathcal{A}$  takes  $x$  as an input and runs relative to  $\mathcal{O}$ .

*Example: Quantum oracle of a fixed function and a quantum random oracle.* According to the above model, the quantum oracle  $\mathcal{O}_f$  of a fixed function  $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$  is modeled as follows: the state space of  $\mathcal{O}_f$  is empty. The unitary operator  $O_f$  that processes queries made to  $\mathcal{O}_f$  is defined by  $O_f : |x\rangle|y\rangle \mapsto |x\rangle|y \oplus f(x)\rangle$  for all  $x \in \{0, 1\}^m$  and  $y \in \{0, 1\}^n$ .

In addition, a quantum random oracle (QRO) is defined to be the quantum oracle such that,  $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$  is chosen uniformly at random at the beginning of each game (for some  $m$  and  $n$ ), and quantum oracle access to  $\mathcal{O}_f$  is given to adversaries.

Even if a function  $f$  admits input messages  $M$  and  $M'$  of which lengths differ, we assume that the quantum oracle of  $O_f$  admits queries of superpositions of  $M$  and  $M'$ . In such a case, we assume that length  $|M|$  of each message  $M$  is encoded with  $M$ . However, for ease of notation, we just write  $|M\rangle$  instead of  $|(|M|, M)\rangle$  for each message  $M$ .

## 2.2 How to Model Accesses to Multiple Quantum Oracles

Suppose that an adversary  $\mathcal{A}$  is given oracle accesses to multiple quantum oracles  $\mathcal{O}_1, \dots, \mathcal{O}_s$ , and  $\mathcal{A}$  makes  $q$  queries to each oracle  $\mathcal{O}_1, \dots, \mathcal{O}_s$  in a sequential order. That is, for each  $1 \leq j < s$ , after  $\mathcal{A}$  makes the  $i$ -th query to  $\mathcal{O}_j$ ,  $\mathcal{A}$  performs some offline computations, and then makes the  $i$ -th query to  $\mathcal{O}_{j+1}$ . Similarly, after  $\mathcal{A}$  makes the  $i$ -th query to  $\mathcal{O}_s$ ,  $\mathcal{A}$  performs some offline computations, and then makes the  $(i+1)$ -th query to  $\mathcal{O}_1$ . Here we explain how to model the behavior of  $\mathcal{A}$  and multiple quantum oracles  $\mathcal{O}_1, \dots, \mathcal{O}_s$  as sequential applications of unitary operators, in the case that  $\mathcal{A}$  makes queries in a sequential order as above.

We assume that the oracles share a state space that is described as the tensor product  $\mathcal{H}_{\text{query}} \otimes \mathcal{H}_{\text{answer}} \otimes \mathcal{H}_{\text{state}}$ . Here,  $\mathcal{H}_{\text{query}} \otimes \mathcal{H}_{\text{answer}}$  is the partial state space of  $\mathcal{A}$  (thus the adversary and the oracles share the registers to send queries and

receive answers).  $\mathcal{H}_{\text{state}}$  is oracles' private space that adversaries cannot access directly.

For each quantum oracle  $\mathcal{O}_i$ , let  $O_i$  denote the unitary operator to process queries. We assume that the initial state of  $\mathcal{A}$  is set to be  $|x\rangle$  when  $\mathcal{A}$  takes  $x$  as an input (when  $\mathcal{A}$  does not take any initial input, by convention we assume that the initial state of  $\mathcal{A}$  is  $|0^\alpha\rangle$  for some  $\alpha$ ). Let  $|\text{init}\rangle$  be the initial state of the oracles' private space  $\mathcal{H}_{\text{state}}$ . Then we model that the quantum state of  $\mathcal{A}$  and the oracles before the final measurement becomes  $\left(\prod_{j=1}^q U_{s,j} O_s \cdots U_{1,j} O_1\right) U_0 |x\rangle \otimes |\text{init}\rangle$ , where the adversary  $\mathcal{A}$  is modeled as the sequence of unitary operators  $(U_0, U_{1,1}, \dots, U_{s,1}, U_{1,2}, \dots, U_{s,q})$ , and  $U_{i,j}$  corresponds to the offline computation by  $\mathcal{A}$  after the  $j$ -th query to  $\mathcal{O}_i$ . By  $z \leftarrow \mathcal{A}^{\mathcal{O}_1, \dots, \mathcal{O}_s}(x)$ , we denote the event that  $\mathcal{A}$  finally outputs the classical string  $z$  when  $\mathcal{A}$  takes  $x$  as an input and runs relative to the oracles  $\mathcal{O}_1, \dots, \mathcal{O}_s$ .

**The model of adversaries of which queries are not in a sequential order.**

In the above model we considered the special case that the adversary queries to oracles  $\mathcal{O}_1, \dots, \mathcal{O}_s$  in a sequential order. However, even if an adversary  $\mathcal{B}$  (given oracle accesses to  $\mathcal{O}_1, \dots, \mathcal{O}_s$ ) does not make queries in such a sequential order, the behavior of  $\mathcal{B}$  can be captured with the above model: Suppose that  $\mathcal{B}$  makes at most  $q_i$  quantum queries to  $\mathcal{O}_i$  for each  $i$ , and  $s$  is a constant. Then, we can make another adversary  $\mathcal{A}$  such that  $\mathcal{A}$ 's output distributions are the same as that of  $\mathcal{B}$ , and  $\mathcal{A}$  makes  $O(\max\{q_1, \dots, q_s\})$  queries to each oracle in a sequential order as in the above model, by appropriately increasing the number of queries. Thus all reasonable adversaries are captured by the above model.

**2.3 Security Advantages**

**Quantum distinguishing advantage.** For quantum oracles  $\mathcal{O}_1, \dots, \mathcal{O}_s$  and  $\mathcal{O}'_1, \dots, \mathcal{O}'_s$ , we define the quantum distinguishing advantage of an adversary  $\mathcal{A}$  by  $\text{Adv}_{(\mathcal{O}_1, \dots, \mathcal{O}_s), (\mathcal{O}'_1, \dots, \mathcal{O}'_s)}^{\text{dist}}(\mathcal{A}) := \left| \Pr [1 \leftarrow \mathcal{A}^{\mathcal{O}_1, \dots, \mathcal{O}_s}()] - \Pr [1 \leftarrow \mathcal{A}^{\mathcal{O}'_1, \dots, \mathcal{O}'_s}()] \right|$ .

**qPRF advantage in QROM.** Let  $h$  be a QRO and  $F_K^h$  be a keyed function that may depend on  $h$ . By the same symbol  $F_K^h$  we denote the quantum oracle such that the key  $K$  is chosen at random, and the quantum oracle access to  $F_K^h$  is given to adversaries. In addition, let RF be the quantum oracle of a random function that is independent of  $h$ . Then, we define the quantum pseudorandom function advantage (qPRF advantage) of  $\mathcal{A}$  on  $F_K^h$  by  $\text{Adv}_{F_K^h}^{\text{qPRF}}(\mathcal{A}) := \text{Adv}_{(F_K^h, h), (\text{RF}, h)}^{\text{dist}}(\mathcal{A})$ .

Here we introduce a basic proposition from a previous work [29] for later use.

**Lemma 1 (Lemma 2.2 of [29]).** *Let  $h : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  be a quantum random oracle. For a random key  $K \in \{0, 1\}^k$  ( $k < m + n$ ), define  $F_K^h : \{0, 1\}^{m+n-k} \rightarrow \{0, 1\}^n$  by  $F_K^h(x) = h(x||K)$ . Then, for each adversary  $\mathcal{A}$  that makes at most  $q_h$  quantum queries to  $h$ ,  $\text{Adv}_{F_K^h}^{\text{qPRF}}(\mathcal{A}) \leq O(q_h/2^{k/2})$  holds.*

**qPRG advantage.** Let  $h$  be a quantum random oracle and  $\rho^h : \{0, 1\}^{k_1} \rightarrow \{0, 1\}^{k_2}$  be a function that may depend on  $h$ . Then, we define the quantum PRG advantage  $\text{Adv}_{\rho^h}^{\text{qPRG}}(\mathcal{A})$  of  $\mathcal{A}$  on  $\rho^h$  by  $\text{Adv}_{\rho^h}^{\text{qPRG}}(\mathcal{A}) := \left| \Pr \left[ K_1 \xleftarrow{\mathbb{S}} \{0, 1\}^{k_1} : 1 \leftarrow \mathcal{A}^h(\rho^h(K_1)) \right] - \Pr \left[ K_2 \xleftarrow{\mathbb{S}} \{0, 1\}^{k_2} : 1 \leftarrow \mathcal{A}^h(K_2) \right] \right|$ . In addition, we introduce the following lemma for later use.

**Lemma 2.** *Let  $h : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  be a quantum random oracle, and  $k \leq m$ . Let  $\Delta \in \{0, 1\}^m$  and  $IV \in \{0, 1\}^n$  be public constants such that  $\Delta \neq 0^m$ . Define  $\rho^h : \{0, 1\}^k \rightarrow \{0, 1\}^{2n}$  by  $\rho^h(K) = h(K \| 0^{m-k} \| IV) \| h((K \| 0^{m-k} \oplus \Delta) \| IV)$ . Then, for any quantum adversary  $\mathcal{A}$  that makes at most  $q_h$  quantum queries to  $h$ ,  $\text{Adv}_{\rho^h}^{\text{qPRG}}(\mathcal{A}) \leq O(q_h/2^{k/2})$  holds.*

Lemma 2 can easily be shown by slightly modifying the proof of Lemma 1 (Lemma 2.2 in [29]), but we give a proof in Section B in the appendix for completeness.

### 3 An Overview on How to Record Quantum Queries

Here, we give an overview of the recording standard oracle with errors [18,19], which is an alternative formalization of Zhandry’s compressed oracle technique [33].

**The primal definition of QRO.** Let us begin with recalling the primal definition of QRO (see Section 2 for details). A QRO is the quantum oracle such that

1. a function  $f$  is chosen from  $\text{Func}(\{0, 1\}^m, \{0, 1\}^n)$ , the set of all functions from  $\{0, 1\}^m$  to  $\{0, 1\}^n$ , uniformly at random, and
2. a quantum oracle access to  $f$  is given to adversaries.

Here,  $m$  and  $n$  are positive integers. Note that the quantum oracle of  $f$  is described as the unitary operator  $O_f$  that is defined by  $O_f : |x\rangle |y\rangle \mapsto |x\rangle |y \oplus f(x)\rangle$  for all  $x \in \{0, 1\}^m$  and  $y \in \{0, 1\}^n$ . In the QROM, an adversary  $\mathcal{A}$  makes quantum queries to a QRO (and quantum queries to additional oracles that may depend on the QRO) and finally returns some outputs.

**An alternative view of QRO: the standard oracle.** Here, let us define a quantum oracle named the *standard oracle*, which is an alternative view of QRO. First, suppose that each function  $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$  is encoded into the  $2^m \cdot (n + 1)$ -bit string  $(0 \| f(0)) \| \dots \| (0 \| f(2^m - 1))$ , and identify  $f$  with this bit string<sup>14</sup>. Second, let  $\text{stO}$  be the unitary operator defined by

$$\text{stO} : |x\rangle |y\rangle \otimes |S\rangle \mapsto |x\rangle |y \oplus S_x\rangle \otimes |S\rangle, \quad (2)$$

<sup>14</sup> Here, the bit “0” concatenated with each  $f(i)$  is redundant, but it is necessary so that the notation for  $\text{stO}$  is compatible with that for the recording standard oracle with errors introduced later.

where  $x \in \{0, 1\}^m$ ,  $y \in \{0, 1\}^n$ , and  $S = (b_0 || S_0) || \cdots || (b_{2^m-1} || S_{2^m-1})$  ( $b_i \in \{0, 1\}$  and  $S_i \in \{0, 1\}^n$  for each  $i$ ). Essentially, the operator  $\text{stO}$  does not act on the register for  $b_i$  for each  $i$ ). Then we have  $\text{stO} |x\rangle |y\rangle \otimes |f\rangle = |x\rangle |y \oplus f(x)\rangle \otimes |f\rangle$  for each function  $f$ .

**Definition 2 (Standard oracle).** *The standard oracle is the quantum oracle such that the initial state of the oracle is  $\sum_f \sqrt{1/2^{n2^m}} |f\rangle$  and each quantum query is processed with the unitary operator  $\text{stO}$ .*

By the same symbol  $\text{stO}$  we denote not only the unitary operator (2) but also the standard oracle if it will cause no confusion. The following lemma clearly holds.

**Lemma 3.** *For any quantum algorithm  $\mathcal{A}$  and any possible output  $z$  (classical bit string),  $\Pr [z \leftarrow \mathcal{A}^{\text{QRO}}] = \Pr [z \leftarrow \mathcal{A}^{\text{stO}}]$  holds.*

**The recording standard oracle with errors.** Let  $\text{IH}$ ,  $U_{\text{toggle}}$ , and  $\text{CH}$  be the unitary operators that act on  $2^m \cdot (n+1)$ -qubit states defined by  $\text{IH} := (I \otimes H^{\otimes n})^{2^m}$ ,  $U_{\text{toggle}} := (I_1 \otimes |0^n\rangle \langle 0^n| + X \otimes (I_n - |0^n\rangle \langle 0^n|))^{2^m}$ , and  $\text{CH} := (\text{CH})^{2^m}$ . Here,  $X$  is the 1-qubit bit-flip operation such that  $X|b\rangle = |b \oplus 1\rangle$  and  $\text{CH} := |0\rangle \langle 0| \otimes I_n + |1\rangle \langle 1| \otimes H^{\otimes n}$ . Let  $U_{\text{enc}} := \text{CH} \cdot U_{\text{toggle}} \cdot \text{IH}$  and  $U_{\text{dec}} := U_{\text{enc}}^*$ , and define the unitary operator  $\text{RstOE}$  that acts on  $(m+n+(n+1) \cdot 2^m)$ -qubit quantum states by

$$\text{RstOE} := (I_{m+n} \otimes U_{\text{enc}}) \cdot \text{stO} \cdot (I_{m+n} \otimes U_{\text{dec}}). \quad (3)$$

Then the recording standard oracle with errors  $\text{RstOE}$  is defined as follows.

**Definition 3 (Recording standard oracle with errors).** *The recording standard oracle with errors is the quantum oracle such that its initial state is  $|0^{2^m(n+1)}\rangle$  and each quantum query is processed with the unitary operator  $\text{RstOE}$ .*

By the same symbol  $\text{RstOE}$  we denote not only the unitary operator (3) but also the recording standard oracle with errors if it will cause no confusion.

*Intuition behind the definition of  $\text{RstOE}$ .*  $\text{RstOE}$  is the composition of  $U_{\text{dec}}$ ,  $\text{stO}$ , and  $U_{\text{enc}}$ . The first operator  $U_{\text{dec}}$  decodes superpositions of databases into the uniform superposition of all functions  $\sum_f \sqrt{1/2^{n2^m}} |f\rangle$ . The second  $\text{stO}$  responds to queries in the same way as the original standard oracle. Finally,  $U_{\text{enc}}$  encodes the uniform superposition of functions into a superposition of databases. Recall that  $U_{\text{enc}} = \text{CH} \cdot U_{\text{toggle}} \cdot \text{IH}$ . Intuitively, after the action of the first unitary operator  $\text{IH}$ , the register of the function  $f$  that corresponds to the value  $f(x)$  changes to  $|0^n\rangle$  if adversary has no information on  $f(x)$ , and changes to some non-zero value if adversary has some information on  $f(x)$ . If the value of the register is non-zero, database should record the value of  $f(x)$ . The second operator  $U_{\text{toggle}}$  checks if the register is non-zero, and set  $b_x := 1$  to indicate that “the value of  $f(x)$  should be recorded”. Finally, the third operator  $\text{CH}$  constructs a (superposition of) database  $D$  in such a way that the value  $f(x)$  is recorded in  $D$  if and only if  $b_x = 1$ .

Next, we give some notation used to describe the property of RstOE. Let  $D := (b_0||y_0)||\cdots||(b_{2^m-1}||y_{2^m-1})$  be a  $2^m \cdot (n+1)$ -bit bit string, where  $b_i \in \{0, 1\}$  and  $y_i \in \{0, 1\}^n$  for  $0 \leq i \leq 2^m - 1$ . We call  $D$  a *valid database* if  $\neg(b_i = 0 \wedge y_i \neq 0^n)$  holds for all  $i$ . If  $b_i = 0 \wedge y_i \neq 0^n$  holds for some  $i$ , we call  $D$  an *invalid database*. Intuitively, a valid database  $D$  will be a quantum version of “transcript” for a random oracle:  $b_x = 1 \wedge y_x = y$  implies that “the adversary queried  $x$  to the random oracle before, and the query was responded with  $y$ ”.

Let  $D = (b_0||y_0)||\cdots||(b_{2^m-1}||y_{2^m-1})$  be a valid database, and  $I_D \subset \{0, 1\}^m$  be the set of indices such that  $i \in I_D$  if and only if  $b_i = 1$ . Then, we can define a set  $S_D \subset \{0, 1\}^m \times \{0, 1\}^n$  from  $D$  by  $S_D := \{(i, y_i)\}_{i \in I_D}$ . Similarly, if a subset  $S \subset \{0, 1\}^m \times \{0, 1\}^n$  satisfies the condition

$$x \neq x' \text{ for distinct elements } (x, s_x), (x', s_{x'}) \in S, \quad (4)$$

we can define a valid database  $D_S$  from  $S$  by  $D_S := (b_0||y_0)||\cdots||(b_{2^m-1}||y_{2^m-1})$ , where  $b_x = 1$  and  $y_x = s_x$  if  $(x, s_x) \in S$  and  $b_x = 0$  and  $y_x = 0^n$  otherwise. Each of the maps  $D \mapsto S_D$  and  $S \mapsto D_S$  is the inverse of the other, and we identify valid databases and the subsets that satisfy (4). Furthermore, we identify a set  $S \subset \{0, 1\}^m \times \{0, 1\}^n$  that satisfies (4) with the partially defined function  $f_S$  such that  $f_S(x) = y$  if and only if  $(x, y) \in S$ , and  $f_S(x) = \perp$  if  $(x, y) \notin S$  for any  $y$ . Particularly, we use the same symbol  $D$  to denote  $S_D$  and  $f_{S_D}$ .

*Remark 3.* Pay attention not to confuse the (valid) databases with the encoding of functions  $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$  that is used when we defined the standard oracle stO. The encoding of functions are used only in the definition of stO, but the notion of databases are used throughout the rest of the paper.

By definition of RstOE, the proposition below immediately follows (see arguments in Section 3 of [18,19] for details).

**Proposition 2.** *The recording standard oracle with errors RstOE is completely indistinguishable from the quantum random oracle. That is, for any quantum algorithm  $\mathcal{A}$  and any possible output  $z$ ,  $\Pr [z \leftarrow \mathcal{A}^{\text{QRO}}] = \Pr [z \leftarrow \mathcal{A}^{\text{RstOE}}]$  holds. In addition, if we measure the database register of RstOE just before  $\mathcal{A}$  makes the  $i$ -th query, the database after the measurement contains at most  $(i - 1)$  entries.*

The following proposition shows the main properties of RstOE that are shown in the previous work [18,19].

**Proposition 3 (Proposition 1 in [18,19]).** *Let  $x \in \{0, 1\}^m$  and  $D = (b_0||y_0)||\cdots||(b_{2^m-1}||y_{2^m-1})$  be a valid database such that  $D(x) = \perp$  (in particular,  $b_x = 0$  and  $y_x = 0^n$  hold). In addition, for  $z \neq 0^n$  let  $D \cup (x, z)^{\text{invalid}}$  be the invalid database  $D \cup (x, z)^{\text{invalid}} := (b'_0||y'_0)||\cdots|(b'_{2^m-1}||y'_{2^m-1})$  such that  $b'_t = b_t \wedge y_t = y'_t$  if  $t \neq x$ , and  $b_x = 0 \wedge y_x = z$ .*

1. For any  $y, \alpha \in \{0, 1\}^n$ , there exists a vector  $|\epsilon_1\rangle$  such that

$$\text{RstOE} |x, y\rangle \otimes |D \cup (x, \alpha)\rangle = |x, y \oplus \alpha\rangle \otimes |D \cup (x, \alpha)\rangle + |\epsilon_1\rangle \quad (5)$$

and  $\|\epsilon_1\| \leq O(\sqrt{1/2^n})$  hold. More precisely,

$$|\epsilon_1\rangle = \frac{1}{\sqrt{2^n}} |x, y \oplus \alpha\rangle \left( |D\rangle - \left( \sum_{\beta \in \{0,1\}^n} \frac{1}{\sqrt{2^n}} |D \cup (x, \beta)\rangle \right) \right) \quad (6)$$

$$- \frac{1}{\sqrt{2^n}} \sum_{\beta \in \{0,1\}^n} \frac{1}{\sqrt{2^n}} |x, y \oplus \beta\rangle (|D \cup (x, \beta)\rangle - |D_\beta^{\text{invalid}}\rangle) \quad (7)$$

$$+ \frac{1}{2^n} |x\rangle |\widehat{0^n}\rangle \left( 2 \sum_{\beta \in \{0,1\}^n} \frac{1}{\sqrt{2^n}} |D \cup (x, \beta)\rangle - |D\rangle \right) \quad (8)$$

holds, where  $|D_\beta^{\text{invalid}}\rangle$  is a superposition of invalid databases for each  $\beta$  defined by  $|D_\beta^{\text{invalid}}\rangle = \sum_{\gamma \neq 0^n} \frac{(-1)^{\beta \cdot \gamma}}{\sqrt{2^n}} |D \cup (x, \gamma)^{\text{invalid}}\rangle$  and  $|\widehat{0^n}\rangle := H^{\otimes n} |0^n\rangle$ .

2. For any  $y$ , there exists a vector  $|\epsilon_2\rangle$  such that

$$\text{RstOE} |x, y\rangle \otimes |D\rangle = \sum_{\alpha \in \{0,1\}^n} \frac{1}{\sqrt{2^n}} |x, y \oplus \alpha\rangle \otimes |D \cup (x, \alpha)\rangle + |\epsilon_2\rangle \quad (9)$$

and  $\|\epsilon_2\| \leq O(\sqrt{1/2^n})$  hold. More precisely,

$$|\epsilon_2\rangle = \frac{1}{\sqrt{2^n}} |x\rangle |\widehat{0^n}\rangle \left( |D\rangle - \sum_{\beta \in \{0,1\}^n} \frac{1}{\sqrt{2^n}} |D \cup (x, \beta)\rangle \right) \quad (10)$$

holds, where  $|\widehat{0^n}\rangle := H^{\otimes n} |0^n\rangle$ .

The first and second properties (especially, (5) and (9)) in this proposition correspond to the classical intuition for lazy sampling such that, when  $x$  is queried to a random function, (i) if  $x$  has been queried before and responded with  $\alpha$ , respond with  $\alpha$  again, and (ii) if  $x$  has not been queried before, sample  $\alpha$  uniformly at random and respond with  $\alpha$ , respectively. This intuition works well when the initial state  $|x, y\rangle \otimes |D \cup (x, \alpha)\rangle$  or  $|x, y\rangle \otimes |D\rangle$  are not superposed. When the initial states are superposed, the effect of the error terms  $|\epsilon_1\rangle$  and  $|\epsilon_2\rangle$  become significant, and quantum-specific property such that “an entry  $(x, \alpha) \in D$  is deleted from  $D$  at a query” or “an entry  $(x, \alpha) \in D$  is overwritten with another data  $(x, \alpha')$  at a query” emerge.

## 4 Technical Proposition

The goal of this section is to show the following proposition, which is the technically hardest part to show quantum security of HMAC and NMAC.<sup>15</sup> Once we prove it, the remaining proofs for HMAC and NMAC can be shown by using simpler techniques. See also Section 1.2 for proof intuition.

<sup>15</sup> The proposition is a formal restatement of Proposition 1 in Section 1.2 for the case  $u \in \{0, 1\}^{n+m'}$ .

**Proposition 4.** Let  $h : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  be a quantum random oracle. Let  $f : \{0, 1\}^{n+m'} \rightarrow \{0, 1\}^n$  be a random function, and  $F_1^h : \{0, 1\}^{n+m'} \times \{0, 1\}^m \rightarrow \{0, 1\}^n$  be the function defined by  $F_1^h(u, v) := h(v, f(u))$ . Let  $\mathcal{A}$  be an algorithm that runs relative to the quantum oracle of  $F_1^h$  and the quantum random oracle  $h$ , or the quantum oracle of a random function RF and the quantum random oracle  $h$ . Suppose that  $\mathcal{A}$  makes at most  $q_h$  quantum queries to  $h$  and  $Q$  quantum queries to  $F_1^h$  or RF. Let  $q := \max\{Q, q_h\}$ , and suppose that  $q$  is in  $o(2^{n/3})$ . Then

$$\mathbf{Adv}_{F_1^h}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\sqrt{q^3/2^n}\right) \quad (11)$$

holds.

Let  $F_2$  be the function defined by  $F_2(u, v) := g(u, v, f(u))$ , where  $g : \{0, 1\}^{n+m'} \times \{0, 1\}^m \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  is another random function. Then, since  $g$  is a random function,  $\mathbf{Adv}_{F_1^h}^{\text{qPRF}}(\mathcal{A}) = \mathbf{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A})$  holds. To simplify proofs, instead of directly showing (11), we show that  $\mathbf{Adv}_{(F_1^h, h), (F_2, h)}^{\text{dist}}(\mathcal{A}) \leq O\left(\sqrt{q^3/2^n}\right)$  holds.

#### 4.1 Proof of Proposition 4

Here we give a proof for the case  $m' = 0$ . The claims for  $m' > 0$  can be shown in the same way. We assume that  $\mathcal{A}$  makes queries to  $F_1^h$  and  $h$  (or,  $F_2$  and  $h$ ) in a sequential order and model the adversary and oracles as in Section 2.2. In particular, by convention we assume that  $\mathcal{A}$ 's  $(2i - 1)$ -th query is made to  $F_1^h$  (or  $F_2$ ) and  $2i$ -th query is made to  $h$  for  $1 \leq i \leq q$ . (For instance,  $\mathcal{A}$  first queries to  $F_1^h$  (or  $F_2$ ) and second queries to  $h$ .) We call queries to  $F_1^h$  and  $F_2$  *online queries* and queries to  $h$  *offline queries* since, in practical settings, computations of  $h$  are done offline on adversaries' (quantum) computers.

We assume that the unitary operators to process queries to  $F_1^h$  and  $F_2$  are implemented as follows:

*Quantum oracle of  $F_1^h$ .*

1. Take  $|u, v\rangle |y\rangle$  as an input, where  $u, y \in \{0, 1\}^n$  and  $v \in \{0, 1\}^m$ .
2. Query  $u$  to  $f$  and obtain

$$|u, v\rangle |y\rangle \otimes |f(u)\rangle. \quad (12)$$

3. Query  $(v, f(u))$  to  $h$  and add the answer into the  $y$  register to obtain

$$|u, v\rangle |y \oplus F_1^h(u, v)\rangle \otimes |f(u)\rangle. \quad (13)$$

4. Uncompute Step 2 to obtain  $|u, v\rangle |y \oplus F_1^h(u, v)\rangle$ .

We assume that the quantum oracle of  $F_2$  is implemented in the same way as  $F_1^h$ , except that the query  $(v, f(u))$  to  $h$  in Step 3 is replaced with the query  $(u, v, f(u))$  to  $g$ . See also Figure 5.

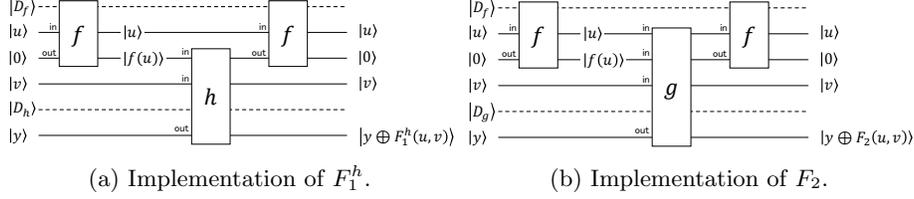

Fig. 5: Implementations of  $F_1^h$  and  $F_2$ . “in” and “out” denote the registers to send queries and receive answers, respectively. The dotted lines (and  $|D_f\rangle, |D_h\rangle, |D_g\rangle$ ) appear only when  $f, h, g$  are implemented with RstOE, which correspond to the database registers.

We show the hardness of distinguishing  $F_1^h$  and  $F_2$  by using the recording standard oracle with errors (RstOE): We assume that the quantum oracles of  $f, g$ , and  $h$  are implemented by using RstOE (quantum queries are processed with RstOE). Let  $\text{RstOE}_f, \text{RstOE}_g$ , and  $\text{RstOE}_h$  be the recording standard oracle with errors for  $f, g$ , and  $h$ , respectively. We use the symbols  $D_f, D_g$ , and  $D_h$  to denote databases for  $f, g$ , and  $h$ , respectively. Then the unitary operator  $O_{F_1^h}$  (resp.,  $O_{F_2}$ ) to process queries to  $F_1^h$  (resp.,  $F_2$ ) can be decomposed as  $O_{F_1^h} = \text{RstOE}_f^* \cdot \text{RstOE}_h \cdot \text{RstOE}_f$  (resp.,  $O_{F_2} = \text{RstOE}_f^* \cdot \text{RstOE}_g \cdot \text{RstOE}_f$ ). See also Figure 5 for the intuition about which registers the different RstOEs act.

**Good and bad databases.** Here we introduce the notion of good and bad databases for  $F_1^h$  and  $F_2$ . When we use the symbols  $u, \zeta, v, w$ , we assume that  $u, \zeta, w \in \{0, 1\}^n$  and  $v \in \{0, 1\}^m$ . We say that a pair of valid database  $(D_f, D_h)$  for  $F_1^h$  is *good* if and only if the following properties are satisfied.

1. For each  $(u, \zeta) \in D_f$ , there exist  $v \in \{0, 1\}^m$  and  $w \in \{0, 1\}^n$  such that  $((v, \zeta), w) \in D_h$ .
2. For  $(u, \zeta)$  and  $(u', \zeta')$  in  $D_f$  such that  $u \neq u', \zeta \neq \zeta'$  holds (there is no collision for  $f$ ).

We say that  $(D_f, D_h)$  is *bad* if it is not good.

Similarly, we say that a tuple of valid databases  $(D_f, D_g, D_h)$  for  $F_2$  is *good* if and only if the following properties are satisfied.

1. For each  $(u, \zeta) \in D_f$ , there exist  $v \in \{0, 1\}^m$  and  $w \in \{0, 1\}^n$  such that  $((u, v, \zeta), w) \in D_g$ .
2. For each  $((u, v, \zeta), w) \in D_g, (u, \zeta) \in D_f$ .
3. For  $(u, \zeta)$  and  $(u', \zeta')$  in  $D_f$  such that  $u \neq u', \zeta \neq \zeta'$  holds (i.e., there is no collision for  $f$ ).
4. For each  $((v, \zeta), w) \in D_h$  and  $(u', \zeta') \in D_f, \zeta \neq \zeta'$  holds (i.e., the most significant  $n$  bits of inputs to  $h$  and the outputs of  $f$  do not collide).

We say that  $(D_f, D_g, D_h)$  is *bad* if it is not good.

*Intuition behind good databases.* Intuitively, a database  $(D_f, D_h)$  for  $F_1^h$  is defined to be good if and only if  $D_f$  does not contain collisions (the second condition on  $F_1^h$ ). The first condition on  $F_1^h$  is included so that a weird situation such as “ $u$  has been queried to  $f$ , but  $(v, f(u))$  has not been queried to  $h$  for any  $v$ ” will not happen for good databases. Similarly, a database  $(D_f, D_g, D_h)$  for  $F_2$  is defined to be good if and only if  $D_f$  does not contain collisions (the third condition on  $F_2$ ) and the least significant  $n$  bits of inputs to  $h$  do not collide with outputs of  $f$  (the fourth condition on  $F_2$ ). The first and second conditions on  $F_2$  is included so that weird situations such as “ $u$  has been queried to  $f$ , but  $(u, v, f(u))$  has not been queried to  $g$  for any  $v$ ” or “ $(u, v, \zeta)$  has been queried to  $g$ , but  $u$  has not been queried to  $f$ ” will not happen for good databases.

**One-to-one correspondence for good databases.** For a good database  $(D_f, D_g, D_h)$  for  $F_2$ , let  $D_g \star D_h$  be the valid database for  $h$  such that  $((v, \zeta), w) \in D_g \star D_h$  if and only if  $((v, \zeta), w) \in D_h$  or  $((u, v, \zeta), w) \in D_g$  for some  $u$ . Then  $(D_f, D_g \star D_h)$  becomes a good database for  $F_1^h$ . Let us denote  $(D_f, D_g \star D_h)$  by  $[(D_f, D_g, D_h)]_1$ . Then, it can easily be shown that the map  $[\cdot]_1 : (D_f, D_g, D_h) \mapsto [(D_f, D_g, D_h)]_1 = (D_f, D_g \star D_h)$  is a bijection between the set of good databases for  $F_2$  and that for  $F_1^h$ . Let  $[\cdot]_2$  denote the inverse map of  $[\cdot]_1$ .

The bijections extend to (partially defined) isometries between the state spaces. Let  $\mathcal{H}_{\mathcal{A}}$  be the state space of the adversary, and  $\mathcal{H}_{D_f D_h}$  (resp.,  $\mathcal{H}_{D_f D_g D_h}$ ) be the state space of the databases for  $F_1^h$  (resp.,  $F_2^h$ ). In addition, let  $V_{\text{good}}^{(1)} \subset \mathcal{H}_{D_f D_h}$  (resp.,  $V_{\text{good}}^{(2)} \subset \mathcal{H}_{D_f D_g D_h}$ ) be the subspace spanned by good databases. Then, the linear map from  $\mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(1)}$  to  $\mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(2)}$  that maps  $|\eta\rangle \otimes |D_f, D_h\rangle$  to  $|\eta\rangle \otimes [(D_f, D_h)]_2$  for  $|\eta\rangle \in \mathcal{H}_{\mathcal{A}}$  and a good database  $(D_f, D_h)$  becomes an isometry. We denote this isometry and its inverse also by  $[\cdot]_2$  and  $[\cdot]_1$ , respectively.

**Equivalent good databases.** Next, we define the notion of *equivalent databases*. First, we define the notion for equivalent good databases for  $F_1^h$ . Let  $(D_f, D_h)$  be a good database for  $F_1^h$ , and let

$$S := \{\zeta \in \{0, 1\}^n \mid \exists v, w \text{ s.t. } ((v, \zeta), w) \in D_h \text{ and } (u, \zeta) \notin D_f \text{ for all } u\}.$$

We say that another good database  $(D'_f, D'_h)$  is equivalent to  $(D_f, D_h)$  if and only if they are the same except for the output values of  $f$ , i.e., there exists a permutation  $\pi$  on  $\{0, 1\}^n$  such that

1.  $\pi(\zeta) = \zeta$  for all  $\zeta \in S$ ,
2.  $(u, \zeta) \in D_f$  if and only if  $(u, \pi(\zeta)) \in D'_f$ , and
3.  $((v, \zeta), w) \in D_h$  if and only if  $((v, \pi(\zeta)), w) \in D'_h$  holds.

We define that a good database  $(D'_f, D'_g, D'_h)$  for  $F_2$  is equivalent to another good database  $(D_f, D_g, D_h)$  in the same way, except that  $S$  is defined as  $S := \{\zeta \in \{0, 1\}^n \mid \exists v, w \text{ s.t. } ((v, \zeta), w) \in D_h\}$  and the following condition is additionally imposed.

3<sup>+</sup>.  $((u, v, \zeta), w) \in D_g$  if and only if  $((u, v, \pi(\zeta)), w) \in D'_g$  hold.

As explained in Section 1.2, intuitively, two good databases are defined to be equivalent if and only if any adversary cannot distinguish them. By definition of equivalent databases, if a good database  $(D_f, D_g, D_h)$  for  $F_2$  is equivalent to another good database  $(D'_f, D'_g, D'_h)$ , then  $D'_h = D_h$  holds.

**Notations for state vectors.** Let  $|\phi_{2i-1}\rangle$  be the whole quantum state just before  $\mathcal{A}$ 's  $i$ -th query to  $F_1^h$  when  $\mathcal{A}$  runs relative to  $F_1^h$  and  $h$ . In addition, let  $|\phi_{2i}\rangle$  be the whole quantum state just before  $\mathcal{A}$ 's  $i$ -th query to  $h$  when  $\mathcal{A}$  runs relative to  $F_1^h$  and  $h$ . Define  $|\psi_{2i-1}\rangle$  and  $|\psi_{2i}\rangle$  similarly when  $\mathcal{A}$  runs relative to  $F_2$  and  $h$ . For ease of notation, let  $|\phi_{2q+1}\rangle$  and  $|\psi_{2q+1}\rangle$  be the quantum states just before the final measurement when  $\mathcal{A}$  runs relative to  $(F_1^h, h)$  and  $(F_2, h)$ , respectively.

We will show that Proposition 4 follows from the proposition below.

**Proposition 5.** *For each  $j = 1, \dots, 2q + 1$ , there exist  $|\phi_j^{\text{good}}\rangle, |\phi_j^{\text{bad}}\rangle, |\psi_j^{\text{good}}\rangle$ , and  $|\psi_j^{\text{bad}}\rangle$  that satisfy the following properties:*

1.  $|\phi_j\rangle = |\phi_j^{\text{good}}\rangle + |\phi_j^{\text{bad}}\rangle$  and  $|\psi_j\rangle = |\psi_j^{\text{good}}\rangle + |\psi_j^{\text{bad}}\rangle$ .
2.  $|\phi_j^{\text{good}}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(1)}$  and  $|\psi_j^{\text{good}}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(2)}$ .
3.  $|\phi_j^{\text{good}}\rangle = \left[ |\psi_j^{\text{good}}\rangle \right]_1$ .
4. There exists a complex number  $a_{uvwxyzD_fD_gD_h}^{(j)}$  such that

$$|\psi_j^{\text{good}}\rangle = \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h):\text{good}}} a_{uvwxyzD_fD_gD_h}^{(j)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle \quad (14)$$

and  $a_{uvwxyzD_fD_gD_h}^{(j)} = a_{uvwxyzD'_fD'_gD'_h}^{(j)}$  if  $(D_f, D_g, D_h)$  and  $(D'_f, D'_g, D'_h)$  are equivalent, where  $(u, v)$ ,  $y$ , and  $z$  correspond to  $\mathcal{A}$ 's register to send queries, to receive answers from oracles, and for offline computations, respectively.<sup>16</sup>

5. For a good database  $(D_f, D_g, D_h)$  with non-zero coefficient in  $|\psi_{2i-1}^{\text{good}}\rangle$  (resp., in  $|\psi_{2i}^{\text{good}}\rangle$ ),  $|D_g| \leq i - 1$ ,  $|D_f| \leq 2(i - 1)$ , and  $|D_h| \leq i - 1$  hold (resp.,  $|D_g| \leq i$ ,  $|D_f| \leq 2i$ , and  $|D_h| \leq i - 1$  hold).
6.  $\| |\phi_j^{\text{bad}}\rangle \| \leq \| |\phi_{j-1}^{\text{bad}}\rangle \| + O\left(\sqrt{j/2^n}\right)$  and  $\| |\psi_j^{\text{bad}}\rangle \| \leq \| |\psi_{j-1}^{\text{bad}}\rangle \| + O\left(\sqrt{j/2^n}\right)$  hold (we regard that  $\| |\phi_0^{\text{bad}}\rangle \| = \| |\psi_0^{\text{bad}}\rangle \| = 0$ ).

*Intuitive interpretation of Proposition 5.* The first and second properties show that  $|\phi_j\rangle$  and  $|\psi_j\rangle$  are divided into good and bad components. The third property shows that the good component of  $|\phi_j\rangle$  matches to that of  $|\psi_j\rangle$  through the

<sup>16</sup> To be precise, we have to use the symbol  $(v, \zeta)$  instead of  $(u, v)$  when  $j = 2i$  since we always use the symbol  $v|\zeta$  to denote an input to  $h$ . However, here we use  $(u, v)$  to simplify notations. In the proof we use the symbol  $a_{v\zeta yzD_fD_gD_h}^{(2i)}$  instead of  $a_{uvwxyzD_fD_gD_h}^{(2i)}$ .

isometry  $[\cdot]_1$ , which intuitively means that  $\mathcal{A}$  cannot distinguish the two oracles as long as databases are good. The fourth property shows that the coefficients of equivalent databases are perfectly equal, which intuitively means that  $\mathcal{A}$  cannot distinguish equivalent good databases. The fifth property shows the upper bound of the size of databases. The sixth property shows that the chance for good databases change to bad is very small at each query.

*Overview of the proof of Proposition 5.* The proposition is shown by induction on  $j$ . The claim for  $j = 1$  obviously holds by setting  $|\phi_1^{\text{bad}}\rangle = |\psi_1^{\text{bad}}\rangle = 0$ . Inductive steps are separated into two cases.

(Online queries): If the claim for  $j = 2i - 1$  (i.e., before the  $i$ -th query to  $F_1^h$  or  $F_2$ ) holds, then the claim for  $j = 2i$  (i.e., after the query) holds.

(Offline queries): If the claim for  $j = 2i$  (i.e., before the  $i$ -th query to  $h$ ) holds, then the claim for  $j = 2i + 1$  (i.e., after the query) holds.

Proof for online queries. Recall that  $O_{F_1^h}$  (resp.,  $O_{F_2}$ ) are decomposed as  $O_{F_1^h} = \text{RstOE}_f^* \cdot \text{RstOE}_h \cdot \text{RstOE}_f$  (resp.,  $O_{F_2} = \text{RstOE}_f^* \cdot \text{RstOE}_g \cdot \text{RstOE}_f$ ). We show that Properties 1–6 listed in Proposition 5 hold at each action of  $\text{RstOE}_f$ ,  $\text{RstOE}_h$  (resp.,  $\text{RstOE}_g$ ), and  $\text{RstOE}_f^*$ . A state vector after an action of  $\text{RstOE}$  can be decomposed into three components.<sup>17</sup>

- (i) The one that was (pre-)good before the action and still remains (pre-)good.
- (ii) The one that was (pre-)good before the action but changed to bad.
- (iii) The one that was already bad before the action.

Roughly speaking, we define (i) to be a new good vector, and the sum of (ii) and (iii) to be a new bad vector.<sup>18</sup> Then Properties 1 and 5 of Proposition 5 can easily be shown.

Intuitively, we defined good databases so that the behavior of the oracle of  $F_1^h$  on good databases will be the same for that of  $F_2$  on the corresponding good databases. Thus we can show that Property 3 still holds for the new good vectors by keeping track of how the coefficients of basis vectors change, using Proposition 3.

The intuition for the proof of Property 4 is as follows. Let  $\mathcal{DB}_0 := (D_f, D_g, D_h)$  and  $\mathcal{DB}_1 := (D'_f, D'_g, D'_h)$  (resp.,  $\widetilde{\mathcal{DB}}_0 := (\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  and  $\widetilde{\mathcal{DB}}_1 := (\tilde{D}'_f, \tilde{D}'_g, \tilde{D}'_h)$ ) be equivalent good databases in  $|\psi_{2i-1}^{\text{good}}\rangle$  (resp.,  $|\psi_{2i}^{\text{good}}\rangle$ ). In addition, by  $p_{ij}$  we ambiguously denote the “probability” that  $\mathcal{DB}_i$  changes to  $\widetilde{\mathcal{DB}}_j$  for  $i, j \in \{0, 1\}$  ( $p_{ij}$  has the information on the ratio of the coefficient of the vector corresponding to  $\mathcal{DB}_i$  and that of  $\widetilde{\mathcal{DB}}_j$ ). Then we can show  $p_{ij} = p_{i'j'}$  holds for all  $(i, j), (i', j') \in \{0, 1\} \times \{0, 1\}$  by using symmetry of equivalent databases and

<sup>17</sup> Pre-good databases are defined in the complete proof of Proposition 5 presented in Section C in the appendix.

<sup>18</sup> To be more precise, we sometimes include small “good” terms into the new bad vector so that the analysis will be easier.

Proposition 3. Since the coefficients corresponding to  $\mathcal{DB}_0$  and  $\mathcal{DB}_1$  are equal due to Property 4 on  $|\psi_{2i-1}^{\text{good}}\rangle$ , this implies that Property 4 also holds for  $|\psi_{2i}^{\text{good}}\rangle$ .

Property 6 is proven by showing the norm of the component (iii) is in  $O(\sqrt{i/2^n})$ . Intuitively, this corresponds to showing the probability that the event coll in Section 1.2 happens at the query is  $O(i/2^n)$ . We carefully prove it by using Proposition 3, taking into account that records in databases may be deleted or overwritten.

Proof for offline queries. The proof for offline queries are similar<sup>19</sup>, except that showing  $\|(\text{iii})\| \leq O(\sqrt{i/2^n})$  corresponds to showing  $\Pr[\text{hit}_i] \leq O(i/2^n)$  in Section 1.2. See the explanations around page 11 for the intuition on  $\Pr[\text{hit}_i] \leq O(i/2^n)$ . To formally prove the bound, we use the inductive hypothesis that Property 4 holds for  $j = 2i$ .

See Section C in the appendix for a complete proof.

*Proof (of Proposition 4).* Let  $\text{tr}_{D1}$  (resp.,  $\text{tr}_{D2}$ ) denote the partial trace operations over the quantum states of the databases for  $(F_1^h, h)$  (resp.,  $(F_2, h)$ ). Then

$$\begin{aligned} \text{Adv}_{F_1^h, F_2}^{\text{dist}}(\mathcal{A}) &\leq \text{td}(\text{tr}_{D1}(|\phi_{2q+1}\rangle\langle\phi_{2q+1}|), \text{tr}_{D2}(|\psi_{2q+1}\rangle\langle\psi_{2q+1}|)) \\ &\leq \text{td}\left(\text{tr}_{D1}(|\phi_{2q+1}^{\text{good}}\rangle\langle\phi_{2q+1}^{\text{good}}|), \text{tr}_{D2}(|\psi_{2q+1}^{\text{good}}\rangle\langle\psi_{2q+1}^{\text{good}}|)\right) \end{aligned} \quad (15)$$

$$+ \left\| |\phi_{2q+1}^{\text{bad}}\rangle \right\| + \left\| |\psi_{2q+1}^{\text{bad}}\rangle \right\| \quad (16)$$

holds. By Property 3 of Proposition 5, the term (15) is equal to zero. In addition, (16)  $\leq \sum_{1 \leq j \leq 2q+1} O(\sqrt{j/2^n}) + \sum_{1 \leq j \leq 2q+1} O(\sqrt{j/2^n}) \leq O(\sqrt{q^3/2^n})$  follows from Property 6 of Proposition 5. Hence Proposition 4 follows.  $\square$

## 5 Quantum Security Proofs for HMAC and NMAC

The goal of this section is to show the following proposition.

**Proposition 6.** *Let  $h : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  be a quantum random oracle. Assume  $m \geq n$ . Suppose that the padding function  $\text{pad}$  for the Merkle-Damgård construction is injective and there exists a function  $\mathbf{p} : \mathbb{Z}_{\geq 0} \rightarrow \{0, 1\}^*$  such that  $\text{pad}(M) = M \|\mathbf{p}(|M|\rangle)^{20}$ . Let  $\mathcal{A}$  be a quantum adversary that runs relative to two quantum oracles  $\mathcal{O}^h$  and  $h$ <sup>21</sup> such that (i)  $|\text{pad}(M)| \leq m \cdot \ell$  for arbitrary  $M$  that  $\mathcal{A}$  queries to  $\mathcal{O}^h$  when  $\mathcal{O}^h$  is  $\text{HMAC}_K^h$  or  $\text{NMAC}_{K_1, K_2}^h$ , and (ii)  $\mathcal{A}$  makes at most  $Q$  queries to  $\mathcal{O}^h$  and  $q_h$  queries to  $h$ . Then  $\text{Adv}_{\text{HMAC}_K^h}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\sqrt{\frac{(q_h+Q)^3 \ell^5}{2^n}} + \frac{q_h+Q\ell}{2^{k/2}}\right)$  and  $\text{Adv}_{\text{NMAC}_{K_1, K_2}^h}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\sqrt{\frac{(q_h+Q)^3 \ell^5}{2^n}}\right)$  hold.*

<sup>19</sup> Actually the proof for offline queries are even simpler because the offline oracle is just a single random oracle  $h$  while the online oracles consist of two random functions.

<sup>20</sup> These conditions are satisfied for usual concrete hash functions such as SHA-2. Recall that  $(\{0, 1\}^m)^+$  is the set of bit strings of length positive multiple of  $m$  bits.

<sup>21</sup>  $\mathcal{O}^h$  will be  $\text{HMAC}_K^h$ ,  $\text{NMAC}_{K_1, K_2}^h$ , or a random function.

Recall that  $\text{HMAC}_K^h$  (resp.,  $\text{NMAC}_{K_1, K_2}^h$ ) is the composition of the functions  $\text{MD}^h(\text{IV}, K_{in}||\cdot)$  and  $\text{MD}^h(\text{IV}, K_{out}||\cdot)$  (resp.,  $\text{MD}^h(K_1, \cdot)$  and  $\text{MD}^h(K_2, \cdot)$ ). Let us call the first (resp., second) function the *inner function* (resp., *outer function*). In addition, let  $\text{MD}'^h : \{0, 1\}^n \times (\{0, 1\}^m)^+ \rightarrow \{0, 1\}^n$  be the function that is defined in the same way as  $\text{MD}^h$  but without padding. Then, to prove Proposition 6, it suffices to prove the claim in the case that the inner function of  $\text{HMAC}_K^h$  (resp.,  $\text{NMAC}_{K_1, K_2}^h$ ) is replaced with  $\text{MD}'^h(\text{IV}, K_{in}||\cdot)$  (resp.,  $\text{MD}'^h(K_1, \cdot)$ ) and the lengths of messages queried by  $\mathcal{A}$  is always a multiple of  $m$  and at most  $\ell \cdot m$ , since this change does not decrease adversaries' ability to distinguish.

Thus, in what follows, we prove Proposition 6 in the case where  $\text{HMAC}_K^h$  and  $\text{NMAC}_{K_1, K_2}^h$  are modified as above. We show it by introducing  $(2\ell + 2)$  games  $G_{0,H}, G_{0,N}, G_i$  ( $1 \leq i \leq \ell$ ),  $G'_i$  ( $1 \leq i \leq \ell$ ).

**Game  $G_{0,H}$ .** This is the game that the adversary is given oracle access to the quantum oracle of  $\text{HMAC}_K^h$ , in addition to  $h$ .

**Game  $G_{0,N}$ .** This is the game that the adversary is given oracle access to the quantum oracle of  $\text{NMAC}_{K_1, K_2}^h$ , in addition to  $h$ .

**Game  $G_i$  for  $1 \leq i \leq \ell$ .** In the game  $G_i$ , the adversary is given quantum oracle access to the function  $H_i^h$  (in addition to  $h$ ) that is defined as follows. Let  $M := M[1]||\dots||M[j]$  ( $M[t] \in \{0, 1\}^m$  for each  $t$ ) be an input message for  $H_i^h$ .

1. If  $j < i$ ,  $H_i^h(M) := g_j(M)$  for a random function  $g_j : \{0, 1\}^{mj} \rightarrow \{0, 1\}^n$ .
2. If  $j = i$ ,  $H_i^h(M) := f_{out}(f_i(M))$  for a random function  $f_i : \{0, 1\}^{mi} \rightarrow \{0, 1\}^n$  and  $f_{out} : \{0, 1\}^n \rightarrow \{0, 1\}^n$ .
3. If  $j > i$ , first  $S_i := f_i(M[1]||\dots||M[i])$  is computed, and then  $S_t := h(M[t]||S_{t-1})$  is iteratively computed for  $i < t \leq j$ , and finally  $H_i^h(M)$  is set as  $H_i^h(M) := f_{out}(S_j)$ .

See also Figure 6.

**Game  $G'_i$  for  $1 \leq i \leq \ell$ .** In the game  $G'_i$ , the adversary is given quantum oracle access to the function  $H_i'^h$  (in addition to  $h$ ) that is defined as follows. Let  $M := M[1]||\dots||M[j]$  ( $M[t] \in \{0, 1\}^m$  for each  $t$ ) be an input for  $H_i'^h$ .

1. If  $j \leq i$ ,  $H_i'^h(M) := g_j(M)$  for a random function  $g_j : \{0, 1\}^{mj} \rightarrow \{0, 1\}^n$ .
2. If  $j > i$ , first  $S_i := f_i(M[1]||\dots||M[i])$  is computed, and then  $S_t := h(M[t]||S_{t-1})$  is iteratively computed for  $i < t \leq j$ , and finally  $H_i'^h(M)$  is set as  $H_i'^h(M) := f_{out}(S_j)$ . Here,  $f_i : \{0, 1\}^{mi} \rightarrow \{0, 1\}^n$  and  $f_{out} : \{0, 1\}^n \rightarrow \{0, 1\}^n$  are random functions.

See also Figure 7. Since the lengths of messages queried by  $\mathcal{A}$  is at most  $m \cdot \ell$ ,  $G'_\ell$  becomes the ideal game that  $\mathcal{A}$  runs relative to a random function and  $h$ .

For the distinguishing advantage between  $G_{0,N}$  and  $G_1$  and the distinguishing advantage between  $G_{0,H}$  and  $G_1$ , the following two lemmas hold.

which adversaries can query *only indirectly* in the other construction (i.e.,  $g$  in  $F_2$ ).

2. On the other hand, in Lemma 6, a function to which adversaries can query *only indirectly* in one construction (i.e.,  $f_{out}$  in  $H_i^h$  of  $G_i$ ) is replaced with another function to which adversaries can query *only indirectly* in the other construction (i.e.,  $f'_{out}$  in  $H_i^h$  of  $G'_i$ ).

In the proof of Proposition 4, we had to assure that the probability that an adversary directly queries to  $h$  a value that is recorded in a database is very small (i.e., the probability of the bad event hit in Section 1.2 is very small). This is the reason that we introduced the notion of equivalent databases. On the other hand, in Lemma 6, adversaries can query to both of  $f_{out}$  and  $f'_{out}$  only indirectly (adversaries do not have full control on inputs to  $f_{out}$  and  $f'_{out}$ ). In particular, we can define bad events in Lemma 6 in such a way that whether they happen or not do not depend on the values of  $\mathcal{A}$ 's queries, and their probability can be bounded by using the randomness of outputs of random functions (like  $coll$  in Section 1.2). Therefore we do not have to introduce the notion of equivalent databases in Lemma 6. Hence it is easier to prove Lemma 6 than to prove Proposition 4.

For the distinguishing advantage between  $G'_i$  and  $G_{i+1}$  for  $1 \leq i < \ell$ , the following lemma holds.

**Lemma 7** ( $G'_i$  and  $G_{i+1}$ ).  $\text{Adv}_{(H_i^h, h), (H_{i+1}^h, h)}^{\text{dist}}(\mathcal{A})$  is in  $O\left(\sqrt{(q_h + Q\ell)^3/2^n}\right)$ .

*Proof.* Let  $f'_{i+1} : \{0, 1\}^{m(i+1)} \rightarrow \{0, 1\}^n$  be the function defined by  $f'_{i+1}(M[1] \parallel \dots \parallel M[i+1]) := h(M[i+1] \parallel f_i(M[1] \parallel \dots \parallel M[i]))$ .

For an adversary  $\mathcal{A}$  to distinguish  $(H_i^h, h)$  from  $(H_{i+1}^h, h)$  that makes at most  $Q$  quantum queries to  $H_i^h$  or  $H_{i+1}^h$  and at most  $q_h$  quantum queries to  $h$ , we construct another adversary  $\mathcal{B}$  to distinguish  $(f'_{i+1}, h)$  and  $(f_{i+1}, h)$  by making  $O(Q)$  queries to  $f'_{i+1}$  or  $f_{i+1}$  and  $O(q_h + Q\ell)$  queries to  $h$ , as follows.

$\mathcal{B}$  is given a quantum oracle access to  $\mathcal{O}^h$ , which is  $f'_{i+1}$  or  $f_{i+1}$ , in addition to a quantum oracle access to  $h$ . First,  $\mathcal{B}$  chooses functions  $\tilde{g}_j : \{0, 1\}^{j^m} \rightarrow \{0, 1\}^n$  for  $j = 1, \dots, i$  and  $f_{out} : \{0, 1\}^n \rightarrow \{0, 1\}^n$  uniformly at random, and runs  $\mathcal{A}$ . When  $\mathcal{A}$  makes a query to the second oracle (which is supposed to be  $h$ ),  $\mathcal{B}$  responds by querying to  $h$ . When  $\mathcal{A}$  queries  $M = M[1] \parallel \dots \parallel M[j]$  to the first oracle (which is supposed to be  $H_i^h$  or  $H_{i+1}^h$ ),  $\mathcal{B}$  responds to  $\mathcal{A}$  as follows:

1. If  $j \leq i$ ,  $\mathcal{B}$  computes  $T = \tilde{g}_j(M)$  by itself, and responds to  $\mathcal{A}$  with  $T$ .
2. If  $j > i$ ,  $\mathcal{B}$  computes  $S_{i+1} := \mathcal{O}^h(M)$ ,  $S_u := h(M[u] \parallel S_{u-1})$  for  $u = i + 2, \dots, j$ , and  $T := f_{out}(S_j)$ , by making queries to  $\mathcal{O}^h$  and  $h$ . Then  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $T$ .

Finally,  $\mathcal{B}$  returns  $\mathcal{A}$ 's output as its own output.

Then  $\mathcal{B}$  perfectly simulates  $H_i^h$  or  $H_{i+1}^h$  depending on whether  $\mathcal{O}^h = f'_{i+1}$  or  $\mathcal{O}^h = f_{i+1}$ , which implies that  $\text{Adv}_{(H_i^h, h), (H_{i+1}^h, h)}^{\text{dist}}(\mathcal{A}) = \text{Adv}_{(f'_{i+1}, h), (f_{i+1}, h)}^{\text{dist}}(\mathcal{B})$ .

In addition,  $\mathcal{B}$  makes at most  $O(Q)$  quantum queries to  $f'_{i+1}$  or  $f_{i+1}$  and  $O(q_h +$

$Q\ell$ ) quantum queries to  $h$ . Therefore

$$\mathbf{Adv}_{(H_i^h, h), (H_{i+1}^h, h)}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{(f_{i+1}^h, h), (f_{i+1}, h)}^{\text{dist}}(\mathcal{B}) \leq O\left(\sqrt{\frac{(qh + Q\ell)^3}{2^n}}\right) \quad (17)$$

follows from Proposition 4.  $\square$

*Proof (of Proposition 6).* The claim of the proposition immediately follows from Lemma 4, Lemma 5, Lemma 6, and Lemma 7.  $\square$

## A On Security Bound Given in [31]

This section explains why the result in [31] guarantees security of NMAC up to  $O(2^{n/8})$  or  $O(2^{n/5})$  quantum queries when the compression function is ideally random. (Almost the same arguments apply to HMAC.)

We can reasonably deduce that the security is guaranteed up to  $O(2^{n/8})$  quantum queries, and have the bound  $O(2^{n/5})$  instead of  $O(2^{n/8})$  if we assume a conjecture.

First, we describe the original result on NMAC in the standard model (under the assumption that the compression function is a qPRF), and then translate it into the corresponding claim in the quantum random oracle model where the compression function is a random oracle.

**The original result on NMAC.** Let  $f : \{0, 1\}^m \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be a function, and for each  $K \in \{0, 1\}^n$  let  $f_K(x) = f(x||K)$ . For an adversary  $\mathcal{A}$  and the keyed function  $f_K$ , define the *qPRF advantage under random leakage* by

$$\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(\mathcal{A}) := \left| \Pr [1 \leftarrow \mathcal{A}^{f_K, H}(H(K))] - \Pr [1 \leftarrow \mathcal{A}^{\rho, H}(w)] \right|, \quad (18)$$

where  $\rho : \{0, 1\}^m \rightarrow \{0, 1\}^n$  and  $H : \{0, 1\}^n \rightarrow \{0, 1\}^n$  are random functions, and  $w \stackrel{\$}{\leftarrow} \{0, 1\}^n$ .

In the previous work, Song and Yun showed the following proposition.

**Proposition 7 (Theorem 5.2 in [31]).** *For any adversary  $\mathcal{A}$  that makes at most  $Q$  quantum queries to NMAC or a random function, where the length of each message is upper bounded by  $m \cdot \ell$ , we can construct adversaries  $\mathcal{A}_d$  and  $\mathcal{A}_{rl}$  such that*

$$\mathbf{Adv}_{\text{NMAC}_{K_1, K_2}}^{\text{qPRF}}(\mathcal{A}) \leq \mathbf{Adv}_{f_K}^{\text{qPRF}}(\mathcal{A}_d) + 34(\ell + 1)\sqrt{Q^3 \cdot \mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(\mathcal{A}_{rl})}, \quad (19)$$

where  $\mathcal{A}_d$  makes at most  $Q$  quantum queries to  $f_K$  or a random function, and  $\mathcal{A}_{rl}$  makes at most  $4Q$  queries to  $f_K$  or a random function and at most  $6Q$  queries to  $H$ .

**Translation of Proposition 7 into the QROM.** Now, suppose that  $f$  is a random oracle. Then, similarly to (18), we can define the qPRF advantage under random leakage by

$$\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(\mathcal{A}) := \left| \Pr [1 \leftarrow \mathcal{A}^{f_K, f, H}(H(K))] - \Pr [1 \leftarrow \mathcal{A}^{\rho, f, H}(w)] \right|, \quad (20)$$

where  $\rho : \{0, 1\}^m \rightarrow \{0, 1\}^n$  and  $H : \{0, 1\}^n \rightarrow \{0, 1\}^n$  are random functions that are independent of  $f$ .

In what follows, let us assume  $m = n$  for simplicity. Then, the proposition in the QROM (where the compression function  $f$  is a quantum random oracle) that correspond to Proposition 7 would be like the following proposition, though we do not provide a formal proof.

**Proposition 8.** *For any adversary  $\mathcal{A}$  that makes at most  $Q$  quantum queries to NMAC or a random function and the quantum random oracle  $f$ , where the*

length of each message is upper bounded by  $m \cdot \ell$ , we can construct adversaries  $\mathcal{A}_d$  and  $\mathcal{A}_{rl}$  such that

$$\mathbf{Adv}_{\text{NMAC}_{K_1, K_2}^f}^{\text{qPRF}}(\mathcal{A}) \leq \mathbf{Adv}_{f_K}^{\text{qPRF}}(\mathcal{A}_d) + O\left(\sqrt{\ell^2 Q^3 \cdot \mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(\mathcal{A}_{rl})}\right), \quad (21)$$

where  $\mathcal{A}_d$  makes at most  $O(Q)$  quantum queries to  $f_K$  or a random function and at most  $O(Q)$  quantum queries to the random oracle  $f$ , and  $\mathcal{A}_{rl}$  makes at most  $O(Q)$  quantum queries to  $f_K$  or a random function and at most  $O(Q)$  quantum queries to the random oracles  $f$  and  $H$ .

Let  $\mathbf{Adv}_{f_K}^{\text{qPRF}}(Q) := \max_{\mathcal{A}} \mathbf{Adv}_{f_K}^{\text{qPRF}}(\mathcal{A})$  and  $\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(Q) := \max_{\mathcal{A}} \mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(\mathcal{A})$ , where the maximum is taken over all adversaries that make at most  $Q$  queries to each oracle. Then,

$$\mathbf{Adv}_{f_K}^{\text{qPRF}}(Q) \leq \mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(Q) \quad (22)$$

apparently holds since some information on  $K$  is leaked via  $H$  (when  $\mathcal{A}$  runs relative to  $f_K$ ).

Now, let us assume

$$\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(Q) = \mathbf{Adv}_{f_K}^{\text{qPRF}}(Q),$$

which may overestimate (but never underestimate) the security claim shown in Proposition 8. Then

$$\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(Q) = \mathbf{Adv}_{f_K}^{\text{qPRF}}(Q) \leq O\left(\sqrt{\frac{Q^2}{2^n}}\right) \quad (23)$$

holds by Lemma 1. Therefore,

$$\mathbf{Adv}_{\text{NMAC}_{K_1, K_2}^f}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\sqrt[4]{\frac{\ell^4 \cdot Q^8}{2^n}}\right). \quad (24)$$

follows from (21). When  $\ell = O(1)$ , the inequality (24) guarantees the security of NMAC only up to  $O(2^{n/8})$  queries.

**The bound  $O(2^{n/5})$  based on a conjecture.** The final bound (24) is based on Lemma 1, which provides the current best qPRF security bound of  $f_K$  in the QROM as far as we know. However, we are not sure if the bound is tight because we do not know any distinguishing attack that matches the bound of Lemma 1.

If we assume the following conjecture instead of (23), we obtain the bound  $O(2^{n/5})$  instead of  $O(2^{n/8})$ .

*Conjecture 1.* It holds that  $\mathbf{Adv}_{f_K}^{\text{qPRF-rl}}(Q) = \mathbf{Adv}_{f_K}^{\text{qPRF}}(Q) \leq O(Q^2/2^n)$ .<sup>22</sup>

<sup>22</sup> This bound matches the bound by the Grover search.

If we assume this, from (21) we obtain

$$\mathbf{Adv}_{\text{NMAC}_{K_1, K_2}^f}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\sqrt{\frac{\ell^2 \cdot Q^5}{2^n}}\right) \quad (25)$$

instead of (24). When  $\ell = O(1)$ , the inequality (25) guarantees the security of NMAC only up to  $O(2^{n/5})$  queries.

*Remark 4.* Very roughly speaking, the barrier to achieve an improved result in the standard model when  $f_K$  is a qPRF (instead of the QROM) lies in Theorems 3.3 and 4.5 of the previous work [31]. Intuitively, the theorems enable us to reduce the qPRF security of  $F_1^h$  in our paper (see Section 1.2. In fact “ $h$ ” in Section 1.2 is replaced with “ $f$ ” here) to the qPRF security of  $f_K$ . The theorems are versatile and useful, but the security loss is too large to achieve the tight bound of HMAC (roughly speaking, for an adversary  $\mathcal{A}$  that makes  $q$  queries,  $\mathbf{Adv}_{F_1^h}^{\text{qPRF}}(\mathcal{A})$  is upper bounded by  $\sqrt{q^3 \mathbf{Adv}_{f_K}^{\text{qPRF}}(\mathcal{B})}$  for an adversary  $\mathcal{B}$  that makes  $O(q)$  queries). Either improving the bound of Theorem 3.3 (and Theorem 4.5) or completely different proof idea will be necessary to achieve the tight bound in the standard model.

## B Proof of Lemma 2

The proof in this section is a simple extension of a previous work (the proof of Lemma 2.2 in [29]). In this section we do not use the recording standard oracle with errors.

We use the following lemma.

**Lemma 8 (Lemma C.1 in [31]).** *For a bit string  $K \in \{0, 1\}^k$  that is uniformly chosen at random, let  $\tilde{g}_K : \{0, 1\}^k \rightarrow \{0, 1\}$  be the function such that  $\tilde{g}_K(x) = 1$  if and only if  $x = K$ . In addition, let  $\tilde{g}_\perp : \{0, 1\}^k \rightarrow \{0, 1\}$  be the function such that  $\tilde{g}_\perp(x) = 0$  for all  $x$ . Then, for a quantum adversary  $\mathcal{A}$  that makes at most  $q$  quantum queries to  $\tilde{g}_K$  or  $\tilde{g}_\perp$ ,*

$$\mathbf{Adv}_{g_K, g_\perp}^{\text{dist}}(\mathcal{A}) \leq O\left(\frac{q}{2^{k/2}}\right) \quad (26)$$

holds.

First, we show that the lemma below follows from Lemma 8.

**Lemma 9.** *Let  $\Delta \in \{0, 1\}^m$  be a public constant such that  $\Delta \neq 0^m$  and suppose that  $k \leq m$ . Let  $g_K^{\text{rel}(\Delta)} : \{0, 1\}^m \rightarrow \{0, 1\}$  be the function such that  $g_K^{\text{rel}(\Delta)}(x) = 1$  if and only if  $x = K || 0^{m-k}$  or  $x = (K || 0^{m-k}) \oplus \Delta$  ( $K \in \{0, 1\}^k$  is chosen uniformly at random). In addition, let  $g_\perp : \{0, 1\}^m \rightarrow \{0, 1\}$  be the function such that  $g_\perp(x) = 0$  for all  $x$ . Then, for any quantum adversary  $\mathcal{A}$  that makes at most  $q$  quantum queries to  $g_K^{\text{rel}(\Delta)}$  or  $g_\perp$ ,*

$$\mathbf{Adv}_{g_K^{\text{rel}(\Delta)}, g_\perp}^{\text{dist}}(\mathcal{A}) \leq O\left(\frac{q}{2^{k/2}}\right) \quad (27)$$

holds.

*Proof.* We construct an adversary  $\mathcal{B}$  to distinguish  $\tilde{g}_K$  and  $\tilde{g}_\perp$  that makes at most  $O(q)$  queries from the adversary  $\mathcal{A}$  to distinguish  $g_K^{\text{rel}(\Delta)}$  and  $g_\perp$  as follows:  $\mathcal{B}$  is given access to the quantum oracle of a Boolean function  $G$  ( $G = \tilde{g}_K$  or  $\tilde{g}_\perp$ ). First,  $\mathcal{B}$  runs  $\mathcal{A}$ . When  $\mathcal{A}$  queries  $x$  to its oracle,  $\mathcal{B}$  performs the following procedure and responds to  $\mathcal{A}$ :

1. If  $k < m$ , and both of the least significant  $(m-k)$  bits of  $x$  (which we denote by  $[x]_{\text{lsb}(m-k)}$ ) and  $x \oplus \Delta$  (which we denote by  $[x \oplus \Delta]_{\text{lsb}(m-k)}$ ) are not equal to  $0^{m-k}$ , respond to  $\mathcal{A}$  with 0.
2. If  $k = m$ , or  $[x]_{\text{lsb}(m-k)} = 0^{m-k}$ , or  $[x \oplus \Delta]_{\text{lsb}(m-k)} = 0^{m-k}$ , then:
  - (a) Set  $b_1 \leftarrow 0$  and  $b_2 \leftarrow 0$ .
  - (b) If  $k = m$  or  $[x]_{\text{lsb}(m-k)} = 0^{m-k}$ , query the most significant  $k$  bits of  $x$  (which we denote by  $[x]_{\text{msb}(k)}$ ) to  $G$ , and set  $b_1 \leftarrow G([x]_{\text{msb}(k)})$ .
  - (c) If  $k = m$  or  $[x \oplus \Delta]_{\text{lsb}(m-k)} = 0^{m-k}$ , query the first  $k$  bits of  $x \oplus \Delta$  (which we denote by  $[x \oplus \Delta]_{\text{msb}(k)}$ ) to  $G$ , and set  $b_2 \leftarrow G([x \oplus \Delta]_{\text{msb}(k)})$ .
  - (d) Respond to  $\mathcal{A}$  with  $b_1 \vee b_2$ .

Finally  $\mathcal{B}$  returns  $\mathcal{A}$ 's last output as its own output.

Then,  $\mathcal{B}$  perfectly simulates  $g_K^{\text{rel}(\Delta)}$  or  $g_\perp$  depending on whether  $G = \tilde{g}_K$  or  $\tilde{g}_\perp$ , and  $\mathcal{B}$  makes at most  $O(q)$  quantum queries. Thus

$$\mathbf{Adv}_{g_K^{\text{rel}(\Delta)}, g_\perp}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{\tilde{g}_K, \tilde{g}_\perp}^{\text{dist}}(\mathcal{B}) \leq O\left(\frac{q}{2^{k/2}}\right) \quad (28)$$

follows from Lemma 8.  $\square$

Next we show the following lemma.

**Lemma 10.** *Let  $h : \{0, 1\}^{n+m} \rightarrow \{0, 1\}^n$  be a quantum random oracle, and let  $k \leq m$ . For a randomly chosen key  $K \in \{0, 1\}^k$  and a public constant  $\Delta \in \{0, 1\}^m$  such that  $\Delta \neq 0^m$ , define a keyed function  $F_K^h : \{0, 1\} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  by, for each  $b \in \{0, 1\}$  and  $x \in \{0, 1\}^n$ ,*

$$F_K^h(b, x) := \begin{cases} h(K || 0^{m-k} || x) & \text{if } b = 0, \\ h((K || 0^{m-k} \oplus \Delta) || x) & \text{if } b = 1. \end{cases} \quad (29)$$

*Then, for any quantum algorithm  $\mathcal{A}$  that makes at most  $q_h$  quantum queries to  $h$ ,*

$$\mathbf{Adv}_{F_K^h}^{\text{qPRF}}(\mathcal{A}) \leq O\left(\frac{q_h}{2^{k/2}}\right) \quad (30)$$

*holds.*

*Proof.* Let  $H_0 : \{0, 1\} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  be a random function that is independent of  $h$ . In addition, let  $H_1^{h, H_0} : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  be a function defined by, for each  $\alpha \in \{0, 1\}^m$  and  $x \in \{0, 1\}^n$ ,

$$H_1^{h, H_0}(\alpha || x) := \begin{cases} h(\alpha || x) & \text{if } \alpha \neq K || 0^{m-k} \text{ and } \alpha \neq K || 0^{m-k} \oplus \Delta, \\ H_0(0, x) & \text{if } \alpha = K || 0^{m-k}, \\ H_0(1, x) & \text{if } \alpha = K || 0^{m-k} \oplus \Delta. \end{cases} \quad (31)$$

Then the distribution of the functions  $(F_K^h, h)$  and the distribution of the functions  $(H_0, H_1^{h, H_0})$  are the same. Thus

$$\begin{aligned}
\mathbf{Adv}_{F_K^h}^{\text{qPRF}}(\mathcal{A}) &= \mathbf{Adv}_{(F_K^h, h), (H_0, h)}^{\text{dist}}(\mathcal{A}) \\
&\leq \mathbf{Adv}_{(F_K^h, h), (H_0, H_1^{h, H_0})}^{\text{dist}}(\mathcal{A}) + \mathbf{Adv}_{(H_0, H_1^{h, H_0}), (H_0, h)}^{\text{dist}}(\mathcal{A}) \\
&= \mathbf{Adv}_{(H_0, H_1^{h, H_0}), (H_0, h)}^{\text{dist}}(\mathcal{A})
\end{aligned} \tag{32}$$

holds.

We construct an adversary  $\mathcal{B}$  to distinguish  $g_K^{\text{rel}(\Delta)}$  and  $g_\perp$  from the adversary  $\mathcal{A}$  to distinguish  $(H_0, H_1^{h, H_0})$  and  $(H_0, h)$  as follows:  $\mathcal{B}$  is given access to the quantum random oracle of a Boolean function  $G$  ( $G = g_K^{\text{rel}(\Delta)}$  or  $g_\perp$ ).  $\mathcal{B}$  first samples random functions  $h' : \{0, 1\}^{m+n} \rightarrow \{0, 1\}^n$  and  $H'_0 : \{0, 1\} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$ , and runs  $\mathcal{A}$ . When  $\mathcal{A}$  makes a query to the first oracle (which is supposed to be  $H_0$ ),  $\mathcal{B}$  responds by using  $H'_0$ . When  $\mathcal{A}$  makes a query  $\alpha || x$  ( $\alpha \in \{0, 1\}^m$  and  $x \in \{0, 1\}^n$ ) to the second oracle (which is supposed to be  $H_1^{h, H_0}$  or  $h$ ),  $\mathcal{B}$  runs the following procedure and respond to  $\mathcal{A}$ :

1. Query  $\alpha$  to  $G$ .
2. If  $G(\alpha) = 0$ ,  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $h'(\alpha || x)$ .
3. If  $G(\alpha) = 1$  and  $[\Delta]_{\text{lsb}(m-k)} \neq 0^{m-k}$ , then
  - (a) If  $[\alpha]_{\text{lsb}(m-k)} = 0^{m-k}$ ,  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $H'_0(0, x)$ .
  - (b) If  $[\alpha]_{\text{lsb}(m-k)} \neq 0^{m-k}$ ,  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $H'_0(1, x)$ .
4. If  $G(\alpha) = 1$  and  $[\Delta]_{\text{lsb}(m-k)} = 0^{m-k}$ , then
  - (a) If  $\alpha < \alpha \oplus \Delta$  (here we regard  $\alpha$  and  $\alpha \oplus \Delta$  as integers in  $\{0, \dots, 2^k - 1\}$ ),  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $H'_0(0, x)$ .
  - (b) If  $\alpha > \alpha \oplus \Delta$ ,  $\mathcal{B}$  responds to  $\mathcal{A}$  with  $H'_0(1, x)$ .

Finally  $\mathcal{B}$  returns  $\mathcal{A}$ 's last output as its own output.

Then,  $\mathcal{B}$  perfectly simulates  $(H_0, H_1^{h, H_0})$  and  $(H_0, h)$  depending on whether  $G$  is  $g_K^{\text{rel}(\Delta)}$  or  $g_\perp$ , and  $\mathcal{B}$  makes at most  $O(q_h)$  quantum queries. Thus

$$\mathbf{Adv}_{(H_0, H_1^{h, H_0}), (H_0, h)}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{g_K^{\text{rel}(\Delta)}, g_\perp}^{\text{dist}}(\mathcal{B}) \leq O\left(\frac{q_h}{2^{k/2}}\right) \tag{33}$$

follows from Lemma 9, which completes the proof.  $\square$

Now we show Lemma 2.

*Proof (of Lemma 2).* Lemma 2 immediately follows from Lemma 10, since adversaries to distinguish  $\rho^h(K)$  and a random  $2n$ -bit string can be regarded as special adversaries to distinguish  $F_K^h$  and a random function that query only  $(0, IV)$  and  $(1, IV)$  to  $F_K^h$  (or the random function).  $\square$

## C Proof of Proposition 5

As mentioned in Section 4, we show the proposition by induction on  $j$ . The claim for  $j = 1$  obviously holds by setting  $|\phi_1^{\text{bad}}\rangle = |\psi_1^{\text{bad}}\rangle = 0$ . Inductive steps are separated into the proof for online queries (i.e., the proof for  $j = 2i$  under the hypothesis on  $j = 2i - 1$ ) and the one for offline queries (i.e., the proof for  $j = 2i + 1$  under the hypothesis on  $j = 2i$ ).

First we prove the former by decomposing  $O_{F_1^h}$  (resp.,  $O_{F_2}$ ) as  $O_{F_1^h} = \text{RstOE}_f^* \cdot \text{RstOE}_h \cdot \text{RstOE}_f$  (resp.,  $O_{F_2} = \text{RstOE}_f^* \cdot \text{RstOE}_g \cdot \text{RstOE}_f$ ), and showing Properties 1–6 in the proposition hold at each action of  $\text{RstOE}_f$ ,  $\text{RstOE}_h$  (resp.,  $\text{RstOE}_g$ ), and  $\text{RstOE}_f^*$ . (See also Figure 5 about the decompositions.)

Before providing the proof, we define pre-good and pre-bad databases in addition to good and bad databases, and see that the one-to-one correspondence between good databases and the notions on equivalent databases are naturally extended to pre-good databases.

**Pre-good and pre-bad databases.** We say that a (pair of) valid database  $(D_f, D_h)$  for  $F_1^h$  is *pre-good* if and only if it satisfies the following properties:

1.  $(D_f, D_h)$  is good, or
2. There exists an element  $(u, \zeta) \in D_f$  such that  $(D_f \setminus (u, \zeta), D_h)$  is good and  $((\zeta, v), w) \notin D_h$  for all  $v$  and  $w$ , and  $(u', \zeta) \notin D_f$  for all  $u' \neq u$ .

We say that  $(D_f, D_h)$  is *pre-bad* if it is not pre-good.

Similarly, we say that a (tuple of) valid database  $(D_f, D_g, D_h)$  for  $F_2$  is *pre-good* if and only if it satisfies the following properties:

1.  $(D_f, D_g, D_h)$  is good, or
2. There exists an element  $(u, \zeta) \in D_f$  such that  $(D_f \setminus (u, \zeta), D_g, D_h)$  is good and  $((v, \zeta), w) \notin D_h \wedge ((u, v, \zeta), w) \notin D_g$  holds for all  $v$  and  $w$ , and  $(u', \zeta) \notin D_f$  for all  $u' \neq u$ .

We say that  $(D_f, D_g, D_h)$  is *pre-bad* if it is not pre-good.

*Intuition behind pre-good databases.* Intuitively, a database is pre-good if and only if one of the following conditions hold: (i) It is just good, or (ii)  $\mathcal{A}$  queried some value  $(u, v)$  to  $F_1^h$  (resp.,  $F_2$ ), the query  $u$  to  $f$  has already been processed inside  $F_1^h$  (resp.,  $F_2$ ) and a new output value  $f(u)$  is sampled but the query  $(v, f(u))$  to  $h$  (resp.,  $(u, v, f(u))$  to  $g$ ) has not been processed yet, and the database is likely to become good.

**One-to-one correspondence for pre-good databases.** Here we re-define the one-to-one correspondence and the isometries  $[\cdot]_1$  and  $[\cdot]_2$  so that they are defined not only on good databases but also on pre-good databases.

For a pre-good database  $(D_f, D_g, D_h)$  for  $F_2$ , let  $D_g \star D_h$  be the valid database for  $h$  such that  $((v, \zeta), w) \in D_g \star D_h$  if and only if  $((v, \zeta), w) \in D_h$  or

$((u, v, \zeta), w) \in D_g$  for some  $u$ . Then  $(D_f, D_g \star D_h)$  becomes a pre-good database for  $F_1^h$ . Let us denote  $(D_f, D_g \star D_h)$  by  $[(D_f, D_g, D_h)]_1$ . Then, it can easily be shown that the map  $[\cdot]_1 : (D_f, D_g, D_h) \mapsto [(D_f, D_g, D_h)]_1 = (D_f, D_g \star D_h)$  is a bijection between the set of pre-good databases for  $F_2$  and the set of pre-good databases for  $F_1^h$ . Let  $[\cdot]_2$  denote the inverse map of  $[\cdot]_1$ .

The bijections extend to (partially defined) isometries between the state spaces. Again, let  $\mathcal{H}_A$  denote the state space of the adversary, and  $\mathcal{H}_{D_f D_h}$  (resp.,  $\mathcal{H}_{D_f D_g D_h}$ ) denote the state space of the databases for  $F_1^h$  (resp.,  $F_2^h$ ). In addition, let  $V_{\text{pre-good}}^{(1)} \subset \mathcal{H}_{D_f D_h}$  (resp.,  $V_{\text{pre-good}}^{(2)} \subset \mathcal{H}_{D_f D_g D_h}$ ) be the subspace spanned by pre-good databases. Let  $\mathcal{H}_{\text{aux}}$  be the state space that corresponds to the auxiliary qubits used by the oracles (see (12) and (13)). Then, the linear map from  $\mathcal{H}_A \otimes V_{\text{pre-good}}^{(1)} \otimes \mathcal{H}_{\text{aux}}$  to  $\mathcal{H}_A \otimes V_{\text{pre-good}}^{(2)} \otimes \mathcal{H}_{\text{aux}}$  that maps  $|\eta\rangle \otimes |D_f, D_h\rangle \otimes |\xi\rangle$  to  $|\eta\rangle \otimes |[D_f, D_h]_2\rangle \otimes |\xi\rangle$  for  $|\eta\rangle \in \mathcal{H}_A$ ,  $|\xi\rangle \in \mathcal{H}_{\text{aux}}$ , and a pre-good database  $(D_f, D_h)$  becomes an isometry. We denote this isometry and its inverse also by  $[\cdot]_2$  and  $[\cdot]_1$ , respectively.

The above mappings  $[\cdot]_1$  and  $[\cdot]_2$  are generalizations of those on good databases define in Section 4. Note that  $[(D_f, D_g, D_h)]_1$  is good if and only if  $(D_f, D_g, D_h)$  is good.

**Equivalent pre-good databases.** Let  $(D_f, D_h)$  be a good database for  $F_1^h$ . Recall that another good database  $(D'_f, D'_h)$  is equivalent to  $(D_f, D_h)$  if and only if they are the same except the output values of  $f$ , i.e., there exists a permutation  $\pi$  on  $\{0, 1\}^n$  such that

1.  $\pi(\zeta) = \zeta$  for all  $\zeta \in S$ ,
2.  $(u, \zeta) \in D_f$  if and only if  $(u, \pi(\zeta)) \in D'_f$ , and
3.  $((v, \zeta), w) \in D_h$  if and only if  $((v, \pi(\zeta)), w) \in D'_h$  hold,

where

$$S := \{\zeta \in \{0, 1\}^n \mid \exists v, w \text{ s.t. } ((v, \zeta), w) \in D_h \text{ and } (u, \zeta) \notin D_f \text{ for all } u\}.$$

Next, we extend the notion for pre-good databases for  $F_1^h$ . By definition, arbitrary pre-good database has the form  $(D_f \cup (u, \zeta), D_h)$  such that  $(D_f, D_h)$  is good. Let  $(D'_f \cup (u', \zeta'), D'_h)$  be another pre-good database such that  $(D'_f, D'_h)$  is good. We say that  $(D_f \cup (u, \zeta), D_h)$  is equivalent to  $(D'_f \cup (u', \zeta'), D'_h)$  if and only if

4.  $(D_f, D_h)$  is equivalent to  $(D'_f, D'_h)$  in the above sense, and
5.  $u = u' \wedge \zeta' = \pi(\zeta)$ , where  $\pi$  is the permutation defined above for  $(D_f, D_h)$ .

We define that a pre-good database  $(D'_f, D'_g, D'_h)$  for  $F_2$  is equivalent to another pre-good database  $(D_f, D_g, D_h)$  in the same way, except that  $S$  is defined as  $S := \{\zeta \in \{0, 1\}^n \mid \exists v, w \text{ s.t. } ((v, \zeta), w) \in D_h\}$  and the following condition is additionally imposed.

- 3<sup>+</sup>.  $((u, v, \zeta), w) \in D_g$  if and only if  $((u, v, \pi(\zeta)), w) \in D'_g$  hold.

**Regular and irregular states.** Let  $|\phi\rangle$  be a joint quantum state of  $\mathcal{A}$  and the oracle  $((F_1^h, h)$  or  $(F_2, h))$  that is not in superposition<sup>23</sup>. We say that the state  $|\phi\rangle$  is *irregular* when the database in  $|\phi\rangle$  is invalid, or the auxiliary  $n$  qubits that are temporarily used in the oracle (the rightmost register  $|f(u)\rangle$  in (12) and (13)) is not  $|0^n\rangle$ . We say that  $|\phi\rangle$  is *regular* if it is not irregular.

**Remarks on other notations.** In what follows, to simplify notations on summations, we denote the sum over variables  $x_1, \dots, x_s$  that satisfies predicates  $P_1(x_1, \dots, x_s), \dots, P_t(x_1, \dots, x_s)$  by  $\sum_{x_1, \dots, x_s; P(x_1, \dots, x_s), \dots, P_t(x_1, \dots, x_s)}$ . That is, we separate the symbols of variables over which the summation is taken and the conditions that the variables satisfy by “;”. For example, the summation over  $\alpha, \beta, \gamma \in \{0, 1\}^n$  that satisfy  $\alpha \oplus \beta = 0^n$  and  $\beta \oplus \gamma = 0^n$  is denoted by  $\sum_{\alpha, \beta, \gamma; \alpha \oplus \beta = 0^n, \beta \oplus \gamma = 0^n}$ .

Let  $\Pi_{\text{valid}}$  and  $\Pi_{\text{invalid}}$  denote the orthogonal projections onto the vector space spanned by valid and invalid databases, respectively. Let  $\Pi_{\text{good}}$  and  $\Pi_{\text{bad}}$  denote the orthogonal projections onto the vector space spanned by good and bad databases, respectively. Let  $\Pi_{\text{pre-good}}$  and  $\Pi_{\text{pre-bad}}$  denote the orthogonal projections onto the vector space spanned by pre-good and pre-bad databases, respectively. Let  $\Pi_{\text{reg}}$  and  $\Pi_{\text{irr}}$  denote the orthogonal projections onto the vector space spanned by regular and irregular databases, respectively.

*Remark 5.* Note that a good database can be pre-good and *bad* because the set of pre-good databases is wider than that of good databases, and we say that a database is bad if it is not good. In the proofs below, we sometimes use the fact that  $\Pi_{\text{bad}}|D_f, D_g, D_h\rangle = |D_f, D_g, D_h\rangle$  (resp.,  $\Pi_{\text{bad}}|D_f, D_h\rangle = |D_f, D_h\rangle$ ) holds for a database  $(D_f, D_g, D_h)$  (resp.,  $(D_f, D_h)$ ) that is *pre-good and bad*, without any notice.

Next we prove the following lemma, which shows how the quantum states  $|\phi_{2i-1}^{\text{good}}\rangle$  and  $|\psi_{2i-1}^{\text{good}}\rangle$  change when  $\text{RstOE}_f$  acts on them.

**Lemma 11 (Action of  $\text{RstOE}_f$ ).** *Suppose that there exist  $|\phi_{2i-1}^{\text{good}}\rangle$ ,  $|\phi_{2i-1}^{\text{bad}}\rangle$ ,  $|\psi_{2i-1}^{\text{good}}\rangle$ , and  $|\psi_{2i-1}^{\text{bad}}\rangle$  that satisfy the properties of Proposition 5. Then there exist  $|\phi_{2i-1}^{\text{good},1}\rangle$ ,  $|\phi_{2i-1}^{\text{bad},1}\rangle$ ,  $|\psi_{2i-1}^{\text{good},1}\rangle$ , and  $|\psi_{2i-1}^{\text{bad},1}\rangle$  that satisfy the following properties:*

1.  $\text{RstOE}_f |\psi_{2i-1}\rangle = |\psi_{2i-1}^{\text{good},1}\rangle + |\psi_{2i-1}^{\text{bad},1}\rangle$  and  $\text{RstOE}_f |\phi_{2i-1}\rangle = |\phi_{2i-1}^{\text{good},1}\rangle + |\phi_{2i-1}^{\text{bad},1}\rangle$ .
2.  $|\phi_{2i-1}^{\text{good},1}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{pre-good}}^{(1)} \otimes \mathcal{H}_{\text{aux}}$  and  $|\psi_{2i-1}^{\text{good},1}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{pre-good}}^{(2)} \otimes \mathcal{H}_{\text{aux}}$ .
3.  $|\phi_{2i-1}^{\text{good},1}\rangle = \left[ |\psi_{2i-1}^{\text{good},1}\rangle \right]_1$ .
4. There exists complex number  $a_{uvyzD_fD_gD_h}^{(2i-1),1}$  such that the following properties
  - (a) and (b) hold:
  - (a) It holds that

$$|\psi_{2i-1}^{\text{good},1}\rangle = \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{pre-good} \\ D_f(u) \neq \perp}} a_{uvyzD_fD_gD_h}^{(2i-1),1} |u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle \otimes |D_f(u)\rangle,$$

<sup>23</sup> That is, even if we measure  $|\phi\rangle$  with computational basis,  $|\phi\rangle$  does not change.

where  $(u, v)$ ,  $y$ , and  $z$  correspond to  $\mathcal{A}$ 's register to send queries, register to receive answers from oracles, and register for offline computations, respectively. (The rightmost register  $|D_f(u)\rangle$  corresponds to the auxiliary qubits used in the oracle. See (12) and (13).)

- (b)  $a_{uvyzD_f D_g D_h}^{(2i-1),1} = a_{uvyzD'_f D'_g D'_h}^{(2i-1),1}$  if  $(D_f, D_g, D_h)$  and  $(D'_f, D'_g, D'_h)$  are equivalent.
5. For a pre-good database  $(D_f, D_g, D_h)$  with non-zero coefficient in  $|\psi_{2i-1}^{\text{good},1}\rangle$ ,  $|D_g| \leq i-1$ ,  $|D_f| \leq 2(i-1)+1$ , and  $|D_h| \leq i-1$  hold.
6.  $\|\phi_{2i-1}^{\text{bad},1}\| \leq \|\phi_{2i-1}^{\text{bad}}\| + O(\sqrt{i/2^n})$  and  $\|\psi_{2i-1}^{\text{bad},1}\| \leq \|\psi_{2i-1}^{\text{bad}}\| + O(\sqrt{i/2^n})$  hold.

*Remark 6.* Intuitive interpretation of the lemma is almost the same as that for Proposition 5 (see the explanation below Proposition 5 for details) except that the fourth property is divided into 4-(a) and 4-(b) in the above lemma, where 4-(a) says that there is an auxiliary register  $D_f(u)$  and the coefficient  $a_{uvyzD_f D_g D_h}^{(2i-1),1}$  in  $|\psi_{2i-1}^{\text{good},1}\rangle$  is non-zero only if  $D_f(u) \neq \perp$ .

*Proof.* First, note that property 3 and 4 of Proposition 5 imply that

$$\begin{aligned} |\phi_{2i-1}^{\text{good}}\rangle &= \left[ |\psi_{2i-1}^{\text{good}}\rangle \right]_1 \\ &= \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h):\text{good}}} a_{uvyzD_f D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_g \star D_h\rangle \end{aligned} \quad (34)$$

holds.

Let  $\Pi_{\perp}$  and  $\Pi_{\neq}$  be the orthogonal projections onto the spaces spanned by the vectors  $|u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle$  (or,  $|u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_h\rangle$ ) such that  $D_f(u) = \perp$  and  $D_f(u) \neq \perp$ , respectively.

Recall that  $|\psi_{2i-1}^{\text{good}}\rangle$  is represented as in (14). By applying the first property in Proposition 3 in a straightforward manner, we have

$$\begin{aligned} &\Pi_{\text{valid}} \text{RstOE}_f \Pi_{\neq} |\psi_{2i-1}^{\text{good}}\rangle \\ &= \Pi_{\text{valid}} \text{RstOE}_f \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h):\text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\ &\quad \otimes |D_f \cup (u, \alpha), D_g, D_h\rangle \\ &= \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h):\text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\ &\quad \otimes |D_f \cup (u, \alpha), D_g, D_h\rangle \otimes |\alpha\rangle \end{aligned} \quad (35)$$

$$\begin{aligned} &+ \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h):\text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\ &\quad \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle \right) |D_g, D_h\rangle \otimes |\alpha\rangle \end{aligned} \quad (36)$$

$$- \sum_{\substack{u,v,y,z,\alpha,\gamma,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{2^n} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u, \gamma), D_g, D_h\rangle \otimes |\gamma\rangle \quad (37)$$

$$+ \frac{1}{2^n} \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes \left( 2 \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle - |D_f\rangle \right) |D_g, D_h\rangle \otimes |\widehat{0^n}\rangle, \quad (38)$$

where the terms (35)-(38) correspond to (5)-(8), respectively. Similarly, by applying the second property in Proposition 3 we have

$$\begin{aligned} & \Pi_{\text{valid}} \text{RstOE}_f \Pi_{\perp} |\psi_{2i-1}^{\text{good}}\rangle \\ &= \Pi_{\text{valid}} \text{RstOE}_f \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f, D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle \\ &= \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f, D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u, \alpha), D_g, D_h\rangle \otimes |\alpha\rangle \quad (39) \\ &+ \frac{1}{\sqrt{2^n}} \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f, D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle \right) |D_g, D_h\rangle \otimes |\widehat{0^n}\rangle, \quad (40) \end{aligned}$$

where the terms (39) and (40) correspond to (9) and (10), respectively. Since (34) holds, in the same way we have

$$\begin{aligned} & \Pi_{\text{valid}} \text{RstOE}_f \Pi_{\not\perp} |\phi_{2i-1}^{\text{good}}\rangle \\ &= \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u, \alpha), D_g \star D_h\rangle \otimes |\alpha\rangle \quad (41) \end{aligned}$$

$$+ \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes \left( |D_f\rangle - \sum_{\gamma} |D_f \cup (u, \gamma)\rangle \right) |D_g \star D_h\rangle \otimes |\alpha\rangle \quad (42)$$

$$- \sum_{\substack{u,v,y,z,\alpha,\gamma,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{2^n} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u, \gamma), D_g \star D_h\rangle \otimes |\gamma\rangle \quad (43)$$

$$\begin{aligned}
& + \frac{1}{2^n} \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\
& \quad \otimes \left( 2 \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle - |D_f\rangle \right) |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle
\end{aligned} \tag{44}$$

and

$$\begin{aligned}
& \Pi_{\text{valid}} \text{RstOE}_f \Pi_{\perp} |\phi_{2i-1}^{\text{good}}\rangle \\
& = \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f, D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_fD_gD_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\
& \quad \otimes |D_f \cup (u, \alpha), D_g \star D_h\rangle \otimes |\alpha\rangle
\end{aligned} \tag{45}$$

$$\begin{aligned}
& + \frac{1}{\sqrt{2^n}} \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f, D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_fD_gD_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \\
& \quad \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle \right) |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle.
\end{aligned} \tag{46}$$

Define  $|\psi_{2i-1}^{\text{good},1}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},1}\rangle$ ,  $|\phi_{2i-1}^{\text{good},1}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},1}\rangle$  by

$$\begin{aligned}
|\psi_{2i-1}^{\text{good},1}\rangle & := |(35)\rangle + \Pi_{\text{pre-good}} |(39)\rangle, & |\psi_{2i-1}^{\text{bad},1}\rangle & := \text{RstOE}_f |\psi_{2i-1}\rangle - |\psi_{2i-1}^{\text{good},1}\rangle, \\
|\phi_{2i-1}^{\text{good},1}\rangle & := |(41)\rangle + \Pi_{\text{pre-good}} |(45)\rangle, & |\phi_{2i-1}^{\text{bad},1}\rangle & := \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},1}\rangle.
\end{aligned}$$

*Remark 7.* The intuition behind the definitions of  $|\psi_{2i-1}^{\text{good},1}\rangle$  is as follows. Roughly speaking, the two terms  $|(35)\rangle$  and  $|(39)\rangle$  reflect classical intuition of lazy sampling, and other terms represent the difference between classical behavior and quantum-specific behavior of oracle. Since now the output of  $f$  is written into the auxiliary register that is set to be 0, the behavior of the  $\text{RstOE}_f$  is very close to that of the classical random oracle, and the effect of quantum-specific behavior of the oracle is very small. Therefore we define  $|\psi_{2i-1}^{\text{good},1}\rangle$  to be the pre-good components of  $|(35)\rangle$  and  $|(39)\rangle$  (note that all the databases in  $|(35)\rangle$  are good and  $\Pi_{\text{pre-good}} |(35)\rangle = |(35)\rangle$  holds).  $|\psi_{2i-1}^{\text{bad},1}\rangle$  is defined in such a way that property 1 of the lemma holds. The intuition behind  $|\phi_{2i-1}^{\text{good},1}\rangle$  and  $|\phi_{2i-1}^{\text{good},1}\rangle$  is the same.

Property 1, 4-(a), 5 of the lemma immediately follow from the definition of  $|\psi_{2i-1}^{\text{good},1}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},1}\rangle$ ,  $|\phi_{2i-1}^{\text{good},1}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},1}\rangle$ .

Property 2 of the lemma holds since all the databases in  $|(35)\rangle$  and  $|(41)\rangle$  are good, and those in  $\Pi_{\text{pre-good}} |(39)\rangle$  and  $\Pi_{\text{pre-good}} |(45)\rangle$  are pre-good.

Property 3 of the lemma holds because, for each basis vector  $|\tilde{u}, \tilde{v}\rangle |\tilde{y}\rangle |\tilde{z}\rangle \otimes |\tilde{D}_f, \tilde{D}_g, \tilde{D}_h\rangle \otimes |\tilde{\gamma}\rangle$  in  $|(35)\rangle$  (resp., in  $\Pi_{\text{pre-good}} |(39)\rangle$ ), its coefficient is equal to the coefficient of  $|\tilde{u}, \tilde{v}\rangle |\tilde{y}\rangle |\tilde{z}\rangle \otimes |\tilde{D}_f, \tilde{D}_g, \tilde{D}_h\rangle \otimes |\tilde{\gamma}\rangle_1 = |\tilde{u}, \tilde{v}\rangle |\tilde{y}\rangle |\tilde{z}\rangle \otimes |\tilde{D}_f, \tilde{D}_g \star \tilde{D}_h\rangle \otimes |\tilde{\gamma}\rangle$  in  $|(41)\rangle$  (resp., in  $\Pi_{\text{pre-good}} |(45)\rangle$ ).

For property 4-(b), note that all the databases in  $|(35)\rangle$  are good while those in  $\Pi_{\text{pre-good}} |(39)\rangle$  are pre-good and bad. In particular, it can be checked that the coefficient  $a_{uvwxyzD_f D_g D_h}^{(2i-1),1}$  in  $|\phi_{2i-1}^{\text{good},1}\rangle$  can be represented as

$$a_{uvwxyzD_f D_g D_h}^{(2i-1),1} = a_{uvwxyzD_f D_g D_h}^{(2i-1)} \text{ if } (D_f, D_g, D_h) \text{ is good,}$$

and

$$a_{uvwxyzD_f D_g D_h}^{(2i-1),1} = \frac{1}{\sqrt{2^n}} a_{uvwxyz(D_f \setminus (u, D_f)) D_g D_h}^{(2i-1)} \text{ if } (D_f, D_g, D_h) \text{ is pre-good and bad,}$$

and  $(D_f \setminus (u, D_f), D_g, D_h)$  is a good database in the latter equation. Therefore property 4-(b) follows from property 4 of Proposition 5.

Below we prove that property 6 of the lemma holds for  $|\phi_{2i-1}^{\text{bad},1}\rangle$  by showing the norms of the terms  $|(42)\rangle - |(44)\rangle$ ,  $\Pi_{\text{pre-good}} |(45)\rangle$ , and  $|(46)\rangle$  are small.<sup>24</sup>

Upper bounding the norm of  $|(42)\rangle$ .

Summands of the term (42) are orthogonal to each other. Hence

$$\begin{aligned} \|(42)\|^2 &\leq O\left(\frac{1}{2^n}\right) \cdot \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvwxyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} \right|^2 \\ &= O\left(\frac{1}{2^n}\right) \cdot \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good}}\rangle \right\|^2 \leq O\left(\frac{1}{2^n}\right) \end{aligned} \quad (47)$$

holds.

Upper bounding the norm of  $|(43)\rangle$ .

We have

$$\begin{aligned} \|(43)\|^2 &= \left\| \sum_{\substack{u,v,y,z,\alpha,\gamma,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{2^n} a_{uvwxyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} |u,v\rangle |y\rangle |z\rangle \right. \\ &\quad \left. \otimes |D_f \cup (u,\gamma), D_g \star D_h\rangle \otimes |\gamma\rangle \right\|^2 \\ &= \sum_{\substack{u,v,y,z,\gamma,D_f; \\ D_f(u)=\perp}} \frac{1}{2^{2n}} \left\| \sum_{\substack{\alpha,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} a_{uvwxyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1)} |D_g \star D_h\rangle \right\|^2 \end{aligned}$$

<sup>24</sup> The term  $\Pi_{\text{pre-good}} |(45)\rangle$  corresponds to the classical situation where a fresh value of  $f$  is sampled and causes a bad event. Other terms correspond to the difference between classical behavior and quantum-specific behavior of the oracle.

$$\begin{aligned}
&= \sum_{\substack{u,v,y,z,\gamma,D_f; \\ D_f(u)=\perp}} \frac{1}{2^{2n}} \sum_{D'_h} \left\| \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} |D'_h\rangle \right\|^2 \\
&= \sum_{\substack{u,v,y,z,\gamma,D_f; \\ D_f(u)=\perp}} \frac{1}{2^{2n}} \sum_{D'_h} \left| \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} \right|^2. \quad (48)
\end{aligned}$$

For each fixed tuple  $(u, \alpha, D_f, D'_h)$ , there exist at most only one pair  $(D_g, D_h)$  such that  $D_g \star D_h = D'_h$  and  $(D_f \cup (u, \alpha), D'_h)$  becomes good. Let us denote this pair by  $(D_g[u, \alpha, D_f, D'_h], D_h[u, \alpha, D_f, D'_h])$  (when such a pair exists). In addition, for each fixed tuple  $(u, D_f, D'_h)$ , the number of  $\alpha$  such that  $(D_f \cup (u, \alpha), D'_h)$  becomes good is at most  $|D'_h| \leq O(i)$ . Therefore, for summands of (48) we have

$$\begin{aligned}
&\sum_{D'_h} \left| \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} \right|^2 \\
&= \sum_{D'_h} \left| \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_g[u,\alpha,D_f,D'_h]D_h[u,\alpha,D_f,D'_h]}^{(2i-1)} \right|^2 \\
&\leq \sum_{D'_h} O(i) \cdot \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_g[u,\alpha,D_f,D'_h]D_h[u,\alpha,D_f,D'_h]}^{(2i-1)} \right|^2 \\
&= O(i) \cdot \sum_{D'_h} \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} \right|^2 \\
&= O(i) \cdot \sum_{\substack{\alpha,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g \star D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} \right|^2, \quad (49)
\end{aligned}$$

where we used convexity of quadratic functions for the inequality. From (48) and (49),

$$\| (43) \|^2 \leq O(i) \cdot \sum_{\substack{u,v,y,z,\gamma,D_f; \\ D_f(u)=\perp}} \frac{1}{2^{2n}} \sum_{\substack{\alpha,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g \star D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_g D_h}^{(2i-1)} \right|^2$$

$$\begin{aligned}
&= O\left(\frac{i}{2^n}\right) \cdot \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ D_f(u)=\perp \\ (D_f \cup (u,\alpha), D_g \star D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} \right|^2 \cdot \left( \sum_{\gamma} \frac{1}{2^n} \right) \\
&= O\left(\frac{i}{2^n}\right) \cdot \left\| \Pi_{\perp} | \phi_{2i-1}^{\text{good}} \right\|^2 \cdot 1 \leq O\left(\frac{i}{2^n}\right) \tag{50}
\end{aligned}$$

follows.

Upper bounding the norm of |(44)|.  
On the term (44), we have that

$$\begin{aligned}
\| |(44)| \|^2 &= \frac{1}{2^{2n}} \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \right. \\
&\quad \left. \otimes \left( 2 \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle - |D_f\rangle \right) |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle \right\|^2 \\
&\leq O\left(\frac{1}{2^{2n}}\right) \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \right. \\
&\quad \left. \otimes |D_f\rangle \otimes |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle \right\|^2 \\
&= O\left(\frac{1}{2^{2n}}\right) \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ D_f(u)=\perp}} \left| \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} \right|^2 \\
&\leq O\left(\frac{1}{2^{2n}}\right) \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ D_f(u)=\perp}} \left( 2^n \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} \right|^2 \right) \\
&= O\left(\frac{1}{2^n}\right) \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1)} \right|^2 \\
&= O\left(\frac{1}{2^n}\right) \cdot \left\| \Pi_{\perp} | \phi_{2i-1}^{\text{good}} \right\|^2 \leq O\left(\frac{1}{2^n}\right) \tag{51}
\end{aligned}$$

holds, where we used convexity of quadratic functions for the second inequality.

Upper bounding the norm of  $\Pi_{\text{pre-bad}} |(45)|$ .

When  $(D_f, D_g, D_h)$  is good and  $D_f(u) = \perp$ , the number of  $\alpha$  such that  $(D_f \cup$

$(u, \alpha), D_g \star D_h$ ) becomes pre-bad is at most  $|D_f| + |D_h| \leq O(i)$ . Therefore,

$$\begin{aligned}
\| \Pi_{\text{pre-bad}} |(45)\rangle \|^2 &= \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-bad}}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u, \alpha), D_g \star D_h\rangle \otimes |\alpha\rangle \right\|^2 \\
&= \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f D_g D_h}^{(2i-1)} \right|^2 \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-bad}}} \frac{1}{2^n} \\
&\leq O\left(\frac{i}{2^n}\right) \cdot \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f D_g D_h}^{(2i-1)} \right|^2 \\
&= O\left(\frac{i}{2^n}\right) \cdot \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good}}\rangle \right\|^2 \leq O\left(\frac{i}{2^n}\right) \tag{52}
\end{aligned}$$

holds.

Upper bounding the norm of  $|(46)\rangle$ .

For the term (46), since the summands are orthogonal to each other we have

$$\begin{aligned}
\| |(46)\rangle \|^2 &= \left\| \frac{1}{\sqrt{2^n}} \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f D_g D_h}^{(2i-1)} |u, v\rangle |y\rangle |z\rangle \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle \right) |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle \right\|^2 \\
&\leq O\left(\frac{1}{2^n}\right) \cdot \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f D_g D_h}^{(2i-1)} \right|^2 \\
&= O\left(\frac{1}{2^n}\right) \cdot \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good}}\rangle \right\|^2 \leq O\left(\frac{1}{2^n}\right) \tag{53}
\end{aligned}$$

holds.

Upper bounding the norm of  $|\phi_{2i-1}^{\text{bad},1}\rangle$ .

Since we always obtain a valid database when we measure  $\text{RstOE}_f |\phi_{2i-1}\rangle$ , we have  $\text{RstOE}_f |\phi_{2i-1}\rangle = \Pi_{\text{valid}} \text{RstOE}_f |\phi_{2i-1}\rangle$ . Thus, from (47), (50), (51), (52), and (53).

$$\left\| |\phi_{2i-1}^{\text{bad},1}\rangle \right\| = \left\| \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},1}\rangle \right\|$$

$$\begin{aligned}
&= \left\| \Pi_{\text{valid}} \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},1}\rangle \right\| \\
&\leq \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| + \left\| \Pi_{\text{valid}} \text{RstOE}_f |\phi_{2i-1}^{\text{good}}\rangle - |\phi_{2i-1}^{\text{good},1}\rangle \right\| \\
&\leq \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| + \left\| (42) \right\| + \left\| (43) \right\| + \left\| (44) \right\| \\
&\quad + \left\| \Pi_{\text{pre-bad}} |(45)\rangle \right\| + \left\| (46) \right\| \\
&\leq \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| + O\left(\sqrt{\frac{i}{2^n}}\right) \tag{54}
\end{aligned}$$

follows. Hence the sixth property of the lemma for  $|\phi_{2i-1}^{\text{bad},1}\rangle$  holds. The sixth property of the lemma for  $|\psi_{2i-1}^{\text{bad},1}\rangle$  can be shown in the same way.  $\square$

Next we prove the following lemma, which shows that the behavior of  $\text{RstOE}_g$  on a pre-good database for  $F_2$  is the same as that of  $\text{RstOE}_h$  on the corresponding pre-good database for  $F_1^h$ .

**Lemma 12.** *Let  $(D_f, D_g, D_h)$  and  $(D'_f, D'_g, D'_h)$  be pre-good databases for  $F_2$ . Then, for each  $u, u', \zeta, \zeta', y, y' \in \{0, 1\}^n$  and  $v, v' \in \{0, 1\}^m$ ,*

$$\begin{aligned}
&\langle u', v', \zeta', y' | \langle D'_f, D'_g, D'_h | \text{RstOE}_g | u, v, \zeta, y \rangle | D_f, D_g, D_h \rangle \\
&= \langle u', v', \zeta', y' | \langle D'_f, D'_g \star D'_h | \text{RstOE}_h | u, v, \zeta, y \rangle | D_f, D_g \star D_h \rangle \tag{55}
\end{aligned}$$

holds, where  $\text{RstOE}_g$  acts on  $|u, v, \zeta, y\rangle$  and  $|D_g\rangle$ , and  $\text{RstOE}_h$  acts on  $|v, \zeta, y\rangle$  and  $|D_g \star D_h\rangle$ . ( $|u, v, \zeta\rangle$  corresponds to an input to  $g$ , and  $|v, \zeta\rangle$  corresponds to an input to  $h$ . The answers to the queries are written (added) to  $|y\rangle$  register.)

*Proof.* Since  $\text{RstOE}_g$  and  $\text{RstOE}_h$  do not change the registers  $|u\rangle$ ,  $|v\rangle$ ,  $|\zeta\rangle$ , and  $|D_f\rangle$ , both sides of (55) are 0 when  $(u, v, \zeta, D_f) \neq (u', v', \zeta', D'_f)$ . Below we show the equation when  $(u, v, \zeta, D_f) = (u', v', \zeta', D'_f)$ .

$\text{RstOE}_g$  does not act on the  $|D_h\rangle$  register. In addition,  $\text{RstOE}_g$  does not affect the register that corresponds to the element  $((\tilde{u}, \tilde{v}, \tilde{\zeta}), \tilde{w})$  in  $D_g$  when  $(\tilde{u}, \tilde{v}, \tilde{\zeta}) \neq (u, v, \zeta)$ . Therefore, it suffices to show the equation when (i)  $D_h = \emptyset$  and  $D_g = \{(u, v, \zeta), w\}$  ( $D_g$  has only a single entry), or (ii)  $D_h = \emptyset$  and  $D_g = \emptyset$ .

In the case (i),  $D_g \star D_h = \{(v, \zeta), w\}$  holds, and the equation (55) follows from the first property in Proposition 3. In the case (ii),  $D_g \star D_h = \emptyset$  holds, and the equation (55) follows from the second property in Proposition 3.  $\square$

Next we prove the following lemma, which shows how the quantum states  $\text{RstOE}_f |\phi_{2i-1}^{\text{good}}\rangle$  and  $\text{RstOE}_f |\psi_{2i-1}^{\text{good}}\rangle$  change when  $\text{RstOE}_h$  and  $\text{RstOE}_g$  act on them.

**Lemma 13 (Actions of  $\text{RstOE}_h$  in  $O_{F_1^h}$  and  $\text{RstOE}_g$  in  $O_{F_2}$ ).** *Suppose that there exist vectors  $|\psi_{2i-1}^{\text{good}}\rangle$ ,  $|\psi_{2i-1}^{\text{bad}}\rangle$ ,  $|\phi_{2i-1}^{\text{good}}\rangle$ , and  $|\phi_{2i-1}^{\text{bad}}\rangle$  that satisfy the properties of Proposition 5. Then there exist  $|\psi_{2i-1}^{\text{good},2}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},2}\rangle$ ,  $|\phi_{2i-1}^{\text{good},2}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},2}\rangle$  that satisfy the following properties.*

1.  $\text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle = |\psi_{2i-1}^{\text{good},2}\rangle + |\psi_{2i-1}^{\text{bad},2}\rangle$  and  $\text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle = |\phi_{2i-1}^{\text{good},2}\rangle + |\phi_{2i-1}^{\text{bad},2}\rangle$  hold.
2.  $|\phi_{2i-1}^{\text{good},2}\rangle \in \mathcal{H}_A \otimes V_{\text{pre-good}}^{(1)} \otimes \mathcal{H}_{\text{aux}}$  and  $|\psi_{2i-1}^{\text{good},2}\rangle \in \mathcal{H}_A \otimes V_{\text{pre-good}}^{(2)} \otimes \mathcal{H}_{\text{aux}}$ .
3.  $|\phi_{2i-1}^{\text{good},2}\rangle = \left[ |\psi_{2i-1}^{\text{good},2}\rangle \right]_1$ .
4. There exists complex number  $a_{uvyzD_f D_g D_h}^{(2i-1),2}$  that satisfies the following properties (a) and (b).
  - (a) It holds that

$$|\psi_{2i-1}^{\text{good},2}\rangle = \sum_{\substack{u,v,y,z,D_f,D_g,D_h \\ (D_f,D_g,D_h): \text{pre-good} \\ D_f(u) \neq \perp}} a_{uvyzD_f D_g D_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle \otimes |D_f(u)\rangle,$$

where  $(u, v)$ ,  $y$ , and  $z$  corresponds  $\mathcal{A}$ 's register to send queries, the register to receive answers from oracles, and the register for offline computations, respectively.

- (b)  $a_{uvyzD_f D_g D_h}^{(2i-1),2} = a_{uvyzD'_f D'_g D'_h}^{(2i-1),2}$  holds if  $(D_f, D_g, D_h)$  and  $(D'_f, D'_g, D'_h)$  are equivalent,
5. For a pre-good database  $(D_f, D_g, D_h)$  with non-zero coefficient in  $|\psi_{2i-1}^{\text{good},2}\rangle$ ,  $|D_g| \leq i$ ,  $|D_f| \leq 2(i-1) + 1$ , and  $|D_h| \leq i-1$  hold.
6.  $\| |\psi_{2i-1}^{\text{bad},2}\rangle \| \leq \| |\psi_{2i-1}^{\text{bad}}\rangle \| + O(\sqrt{i/2^n})$  and  $\| |\phi_{2i-1}^{\text{bad},2}\rangle \| \leq \| |\phi_{2i-1}^{\text{bad}}\rangle \| + O(\sqrt{i/2^n})$  hold.

*Proof.* By Lemma 11, there exist vectors  $|\psi_{2i-1}^{\text{good},1}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},1}\rangle$ ,  $|\phi_{2i-1}^{\text{good},1}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},1}\rangle$  that satisfy the six properties in Lemma 11.

Define  $|\psi_{2i-1}^{\text{good},2}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},2}\rangle$ ,  $|\phi_{2i-1}^{\text{good},2}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},2}\rangle$  by

$$\begin{aligned} |\psi_{2i-1}^{\text{good},2}\rangle &:= \Pi_{\text{valid}} \text{RstOE}_g |\psi_{2i-1}^{\text{good},1}\rangle, \\ |\psi_{2i-1}^{\text{bad},2}\rangle &:= \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle - |\psi_{2i-1}^{\text{good},2}\rangle, \\ |\phi_{2i-1}^{\text{good},2}\rangle &:= \Pi_{\text{valid}} \text{RstOE}_h |\phi_{2i-1}^{\text{good},1}\rangle, \\ |\phi_{2i-1}^{\text{bad},2}\rangle &:= \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},1}\rangle. \end{aligned}$$

*Remark 8.* The intuition behind the definition of  $|\psi_{2i-1}^{\text{good},2}\rangle$  is as follows. First, by definition of pre-good databases, all pre-good databases in  $|\psi_{2i-1}^{\text{good},1}\rangle$  remain pre-good (as long as it does not become invalid) after the action of  $\text{RstOE}_g$  due to the following reasoning: If a database in  $|\psi_{2i-1}^{\text{good},1}\rangle$  is pre-good and bad before the query, then the current query to  $\text{RstOE}_g$  is fresh and the database becomes good after the query. If a database in  $|\psi_{2i-1}^{\text{good},1}\rangle$  is good before the query, then the current query to  $\text{RstOE}_g$  has been recorded in  $D_g$ . The record may be overwritten (resp., removed) after the query, but the resulting database remains good (resp., changes to pre-good) by definition of good (resp., pre-good) databases. In particular, databases do not change to pre-bad. Thus we define  $|\psi_{2i-1}^{\text{good},2}\rangle$  as

above.  $|\psi_{2i-1}^{\text{bad},2}\rangle$  is defined so that property 1 of the lemma will hold. The intuition behind the definition of  $|\phi_{2i-1}^{\text{good},2}\rangle$  and  $|\phi_{2i-1}^{\text{good},2}\rangle$  is the same.

Then, property 1, 4-(a), and 5 of the lemma follows by the definition of  $|\psi_{2i-1}^{\text{good},2}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},2}\rangle$ ,  $|\phi_{2i-1}^{\text{good},2}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},2}\rangle$ .

As explained in the above remark, all pre-good database remain pre-good (as long as it does not become invalid) after the action of  $\text{RstOE}_h$  in  $O_{F_1^h}$  (and  $\text{RstOE}_g$  in  $O_{F_2}$ ). Hence property 2 of Lemma 13 follows from property 2 of Lemma 11.

Recall that property 3 of Lemma 11 guarantees that the coefficient of each basis vector in  $|\phi_{2i-1}^{\text{good},1}\rangle$  is equal to that of the corresponding basis vector in  $|\psi_{2i-1}^{\text{good},1}\rangle$ . Lemma 12 assures that the same thing holds for  $|\phi_{2i-1}^{\text{good},1}\rangle$  and  $|\psi_{2i-1}^{\text{good},2}\rangle$ . Hence property 3 of the Lemma 13 also holds.

From property 6 in Lemma 11 it follows that

$$\begin{aligned} & \left\| |\psi_{2i-1}^{\text{bad},2}\rangle \right\| \\ &= \left\| \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle - |\psi_{2i-1}^{\text{good},2}\rangle \right\| \\ &= \left\| \Pi_{\text{valid}} \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle - |\psi_{2i-1}^{\text{good},2}\rangle \right\| \\ &= \left\| \Pi_{\text{valid}} \text{RstOE}_g \left( |\psi_{2i-1}^{\text{good},1}\rangle + |\psi_{2i-1}^{\text{bad},1}\rangle \right) - \Pi_{\text{valid}} \text{RstOE}_g |\psi_{2i-1}^{\text{good},1}\rangle \right\| \\ &\leq \left\| |\psi_{2i-1}^{\text{bad},1}\rangle \right\| \leq \left\| |\psi_{2i-1}^{\text{bad}}\rangle \right\| + O\left(\sqrt{\frac{i}{2^n}}\right) \end{aligned}$$

holds,<sup>25</sup> and similarly  $\left\| |\phi_{2i-1}^{\text{bad},2}\rangle \right\| \leq \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| + O\left(\sqrt{i/2^n}\right)$  also holds. Hence property 6 of Lemma 13 also holds.

In what follows, we show that property 4-(b) of Lemma 13 holds. Suppose that  $(D_f, D_g, D_h)$  and  $(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  are equivalent pre-good databases for  $F_2$  such that  $|D_g| \leq i$ ,  $|D_f| \leq 2(i-1) + 1$ , and  $|D_h| \leq i-1$  hold, and there exists  $u$  such that  $D_f(u) \neq \perp$  and  $\tilde{D}_f(u) \neq \perp$ . Below we show  $a_{uvyzD_f D_g D_h}^{(2i-1),2} = a_{uvyz\tilde{D}_f \tilde{D}_g \tilde{D}_h}^{(2i-1),2}$  for arbitrary  $v, y$ , and  $z$ .

If both of  $(D_f, D_g, D_h)$  and  $(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  are good, then by definition of good databases and definition of equivalent databases, there exists an integer  $s \geq 0$  and  $u_i \in \{0, 1\}^n$ ,  $X_i, Y_i \in \{0, 1\}^n$ ,  $v_i^{(j)} \in \{0, 1\}^m$ ,  $w_i^{(j)} \in \{0, 1\}^n$  for  $i = 1, \dots, s$  and  $j = 1, \dots, t_i$  ( $t_i$  is a positive integer for each  $i$ ) such that

1.  $u_i \neq u_{i'}$ ,  $X_i \neq X_{i'}$ ,  $Y_i \neq Y_{i'}$  for  $i \neq i'$ ,
2.  $v_i^{(j)} \neq v_i^{(j')}$  for each  $i$  and  $j \neq j'$ ,

<sup>25</sup> For the second equality, we used the fact that we always obtain a valid database when we measure the state  $\text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle$ , which implies that  $\text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle = \Pi_{\text{valid}} \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle$  holds.

and

$$D_f = \{(u_i, X_i)\}_{1 \leq i \leq s}, D_g = \left\{ \left( (u_i, v_i^{(j)}, X_i), w_i^{(j)} \right) \right\}_{1 \leq i \leq s, 1 \leq j \leq t_i}, \quad (56)$$

$$\tilde{D}_f = \{(u_i, Y_i)\}_{1 \leq i \leq s}, \tilde{D}_g = \left\{ \left( (u_i, v_i^{(j)}, Y_i), w_i^{(j)} \right) \right\}_{1 \leq i \leq s, 1 \leq j \leq t_i} \quad (57)$$

hold.

If both of  $(D_f, D_g, D_h)$  and  $(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  are pre-good and bad, there exist additional elements  $u_0, X_0, Y_0 \in \{0, 1\}^n$  such that  $u_0 \neq u_i, X_0 \neq X_i, Y_0 \neq Y_i$  for  $i \geq 1$ , and

$$D_f = \{(u_i, X_i)\}_{0 \leq i \leq s}, D_g = \left\{ \left( (u_i, v_i^{(j)}, X_i), w_i^{(j)} \right) \right\}_{1 \leq i \leq s, 1 \leq j \leq t_i}, \quad (58)$$

$$\tilde{D}_f = \{(u_i, Y_i)\}_{0 \leq i \leq s}, \tilde{D}_g = \left\{ \left( (u_i, v_i^{(j)}, Y_i), w_i^{(j)} \right) \right\}_{1 \leq i \leq s, 1 \leq j \leq t_i} \quad (59)$$

hold (note that  $(D_f, D_g, D_h)$  and  $(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  are not equivalent if one of them is good and the other is bad).

Regardless whether  $(D_f, D_g, D_h)$  is good or  $(D_f, D_g, D_h)$  is pre-good and bad, there exists a unique  $i$  such that  $u = u_i$  holds. In addition, there exist a non-negative integer  $s'$  and  $\zeta_1, \dots, \zeta_{s'} \in \{0, 1\}^n, \eta_1, \dots, \eta_{s'} \in \{0, 1\}^m, \xi_1, \dots, \xi_{s'} \in \{0, 1\}^n$  such that

1.  $(\eta_i, \zeta_i) \neq (\eta_{i'}, \zeta_{i'})$  for  $i \neq i'$ ,
2.  $\zeta_i \neq X_\alpha$  and  $\zeta_i \neq Y_\beta$  hold for arbitrary  $i \in \{1, \dots, s'\}$  and  $\alpha, \beta \in \{1, \dots, s\}$ ,

and

$$D_h = \tilde{D}_h = \{((\eta_i, \zeta_i), \xi_i)\}_{1 \leq i \leq s'} \quad (60)$$

holds.

Let  $\pi$  be a permutation on  $\{0, 1\}^n$  such that  $\pi(X_i) = Y_i$  for each  $X_i$  and  $\pi(\zeta_i) = \zeta_i$  for each  $\zeta_i$ . For arbitrary  $D'_g$  such that  $(D_f, D'_g, D_h)$  is pre-good, define a database  $(D''_f, D''_g, D''_h)$  by

1.  $D''_h = D_h$ ,
2.  $D''_f = \tilde{D}_f$ , and
3.  $((u'', v'', \zeta''), w'') \in D''_g$  if and only if  $((u'', v'', \pi^{-1}(\zeta'')), w'') \in D'_g$ .

Then  $(D''_f, D''_g, D''_h)$  is a pre-good database that is equivalent to  $(D_f, D'_g, D_h)$

Let us denote this database  $(D''_f, D''_g, D''_h)$  by  $\pi[D_f, D'_g, D_h]$ .

Since (a) of the fourth property in Lemma 11 holds, by the definition of  $|\psi_{2i-1}^{\text{good}, 2}\rangle$ ,

$$\begin{aligned} & a_{uvyzD_f D_g D_h}^{(2i-1), 2} \\ &= \langle u, v, y, z | \otimes \langle D_f, D_g, D_h | \otimes \langle D_f(u) | |\psi_{2i-1}^{\text{good}, 2}\rangle \\ &= \sum_{\substack{y', D'_g; \\ (D_f, D'_g, D_h): \text{pre-good}}} \langle u, v, y, z | \otimes \langle D_f, D_g, D_h | \otimes \langle D_f(u) | \\ & \quad \text{RstOE}_g |u, v, y', z\rangle \otimes |D_f, D'_g, D_h\rangle \otimes |D_f(u)\rangle \\ & \quad \cdot \langle u, v, y', z | \otimes \langle D_f, D'_g, D_h | \otimes \langle D_f(u) | |\psi_{2i-1}^{\text{good}, 1}\rangle \end{aligned}$$

$$= \sum_{\substack{y', D'_g; \\ (D_f, D'_g, D_h): \text{pre-good}}} c [y', D_f, D'_g, D_h \rightarrow y, D_f, D_g, D_h] \cdot a_{uvy'zD_f D'_g D_h}^{(2i-1),1}$$

follows, where we put

$$\begin{aligned} c [y', D_f, D'_g, D_h \rightarrow y, D_f, D_g, D_h] \\ &:= \langle u, v, y, z | \otimes \langle D_f, D_g, D_h | \otimes \langle D_f(u) | \\ &\quad \text{RstOE}_g |u, v, y', z \rangle \otimes |D_f, D'_g, D_h \rangle \otimes |D_f(u) \rangle. \end{aligned}$$

Now, for arbitrary  $y'$  and  $D'_g$  such that  $(D_f, D'_g, D_h)$  is pre-good,

$$a_{uvy'zD_f D'_g D_h}^{(2i-1),1} = a_{uvy'z\pi[D_f D'_g D_h]}^{(2i-1),1} \quad (61)$$

holds by the fourth property in Lemma 11, and

$$\begin{aligned} c [y', D_f, D'_g, D_h \rightarrow y, D_f, D_g, D_h] \\ = c [y', \pi[D_f, D'_g, D_h] \rightarrow y, \pi[D_f, D_g, D_h]] \end{aligned} \quad (62)$$

follows from the first property of Proposition 3. In addition, the followings hold:

- I.  $\pi[D_f, D_g, D_h] = (\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$  holds.
- II.  $\pi[\cdot]$  is a bijection between the set of pre-good databases of the form  $(D_f, D'_g, D_h)$  (for some  $D'_g$ ) and the set of pre-good databases of the form  $(\tilde{D}_f, D''_g, \tilde{D}_h)$  (for some  $D''_g$ ).

Therefore we have

$$\begin{aligned} &a_{uvyzD_f D_g D_h}^{(2i-1),2} \\ &= \sum_{\substack{y', D'_g; \\ (D_f, D'_g, D_h): \text{pre-good}}} c [y', D_f, D'_g, D_h \rightarrow y, D_f, D_g, D_h] \cdot a_{uvy'zD_f D'_g D_h}^{(2i-1),1} \\ &\stackrel{((61) \text{ and } (62))}{=} \sum_{\substack{y', D'_g; \\ (D_f, D'_g, D_h): \text{pre-good}}} c [y', \pi[D_f, D'_g, D_h] \rightarrow y, \pi[D_f, D_g, D_h]] \cdot a_{uvy'z\pi[D_f D'_g D_h]}^{(2i-1),1} \\ &\stackrel{(\text{from I})}{=} \sum_{\substack{y', D'_g; \\ (D_f, D'_g, D_h): \text{pre-good}}} c [y', \pi[D_f, D'_g, D_h] \rightarrow y, \tilde{D}_f, \tilde{D}_g, \tilde{D}_h] \cdot a_{uvy'z\pi[D_f D'_g D_h]}^{(2i-1),1} \\ &\stackrel{(\text{from II})}{=} \sum_{\substack{y', D''_g; \\ (\tilde{D}_f, D''_g, \tilde{D}_h): \text{pre-good}}} c [y', \tilde{D}_f, D''_g, \tilde{D}_h \rightarrow y, \tilde{D}_f, \tilde{D}_g, \tilde{D}_h] \cdot a_{uvy'z\tilde{D}_f D''_g \tilde{D}_h}^{(2i-1),1} \\ &= a_{uvyz\tilde{D}_f \tilde{D}_g \tilde{D}_h}^{(2i-1),2}, \end{aligned} \quad (63)$$

which shows that property 4-(b) of Lemma 13 also holds.  $\square$

Next we prove the following lemma, which shows how the quantum states  $\text{RstOE}_h \cdot \text{RstOE}_f |\phi_{2i-1}^{\text{good}}\rangle$  and  $\text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}^{\text{good}}\rangle$  change when  $\text{RstOE}_f^*$  acts on them.

**Lemma 14 (Action of  $\text{RstOE}_f^*$ ).** *Suppose that there exist vectors  $|\psi_{2i-1}^{\text{good}}\rangle$ ,  $|\psi_{2i-1}^{\text{bad}}\rangle$ ,  $|\phi_{2i-1}^{\text{good}}\rangle$ , and  $|\phi_{2i-1}^{\text{bad}}\rangle$  that satisfy the sixth properties of Proposition 5. Then there exist vectors  $|\psi_{2i-1}^{\text{good},3}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},3}\rangle$ ,  $|\phi_{2i-1}^{\text{good},3}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},3}\rangle$  that satisfy the following properties:*

1.  $\text{RstOE}_f^* \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle = |\psi_{2i-1}^{\text{good},3}\rangle + |\psi_{2i-1}^{\text{bad},3}\rangle$  holds, and  $\text{RstOE}_f^* \text{RstOE}_h \cdot \text{RstOE}_f |\phi_{2i-1}\rangle = |\phi_{2i-1}^{\text{good},3}\rangle + |\phi_{2i-1}^{\text{bad},3}\rangle$  holds.
2.  $|\phi_{2i-1}^{\text{good},3}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(1)}$  and  $|\psi_{2i-1}^{\text{good},3}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}^{(2)}$ .
3.  $|\phi_{2i-1}^{\text{good},3}\rangle = \left[ |\psi_{2i-1}^{\text{good},3}\rangle \right]_1$ .
4. There exists complex number  $a_{uvyzD_f D_g D_h}^{(2i-1),3}$  such that the following properties (a) and (b) hold:
  - (a) It holds that

$$|\psi_{2i-1}^{\text{good},3}\rangle = \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h):\text{good}}} a_{uvyzD_f D_g D_h}^{(2i-1),3} |u,v\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle, \quad (64)$$

where  $(u, v)$ ,  $y$ , and  $z$  correspond to  $\mathcal{A}$ 's register to send queries, register to receive answers from oracles, and register for offline computations, respectively.

- (b) If  $(D_f, D_g, D_h)$  and  $(D'_f, D'_g, D'_h)$  are equivalent good databases, then  $a_{uvyzD_f D_g D_h}^{(2i-1),3} = a_{uvyzD'_f D'_g D'_h}^{(2i-1),3}$  holds.

5. For a good database  $(D_f, D_g, D_h)$  with non-zero coefficient in  $|\psi_{2i-1}^{\text{good},3}\rangle$ ,  $|D_g| \leq i$ ,  $|D_f| \leq 2i$ , and  $|D_h| \leq i-1$  hold.
6.  $\| |\phi_{2i-1}^{\text{bad},3}\rangle \| \leq \| |\phi_{2i-1}^{\text{bad}}\rangle \| + O\left(\sqrt{i/2^n}\right)$  and  $\| |\psi_{2i-1}^{\text{bad},3}\rangle \| \leq \| |\psi_{2i-1}^{\text{bad}}\rangle \| + O\left(\sqrt{i/2^n}\right)$  hold.

*Proof.* By Lemma 13, there exist vectors  $|\phi_{2i-1}^{\text{good},2}\rangle$ ,  $|\phi_{2i-1}^{\text{bad},2}\rangle$ ,  $|\psi_{2i-1}^{\text{good},2}\rangle$ , and  $|\psi_{2i-1}^{\text{bad},2}\rangle$  that satisfy the six properties in Lemma 13.

For each tuple  $(u, v, y, z, D_f, D_g, D_h)$  such that

1.  $|D_g| \leq i$ ,  $|D_f| \leq 2i$ , and  $|D_h| \leq i-1$ ,
2.  $(D_f, D_g, D_h)$  is good, and
3.  $D_f(u) = \perp$ ,

let  $\alpha$  be an  $n$ -bit string such that  $(D_f \cup (u, \alpha), D_g, D_h)$  is pre-good, and define

$$a_{uvyzD_f D_g D_h}^{(2i-1),3} := \sqrt{2^n} a_{uvyzD_f \cup (u, \alpha) D_g D_h}^{(2i-1),2}. \quad (65)$$

Due to property 4-(b) of Lemma 13, the definition (65) is independent from the choice of  $\alpha$ .

In addition, for each tuple  $(u, v, y, z, D_f, D_g, D_h)$  such that

1.  $|D_g| \leq i$ ,  $|D_f| \leq 2i$ , and  $|D_h| \leq i - 1$  hold,
2.  $(D_f, D_g, D_h)$  is good,
3.  $D_f(u) \neq \perp$ ,

define

$$a_{uvwxyzD_fD_gD_h}^{(2i-1),3} := a_{uvwxyzD_fD_gD_h}^{(2i-1),2}. \quad (66)$$

When the conditions  $|D_g| \leq i$ ,  $|D_f| \leq 2i$ , and  $|D_h| \leq i - 1$  are not satisfied, let

$$a_{uvwxyzD_fD_gD_h}^{(2i-1),3} := 0. \quad (67)$$

Define  $|\psi_{2i-1}^{\text{good},3}\rangle$  by the equation (64), where the coefficients  $a_{uvwxyzD_fD_gD_h}^{(2i-1),3}$  are those defined in (65), (66), and (67). In addition, define  $|\phi_{2i-1}^{\text{good},3}\rangle$  by  $|\phi_{2i-1}^{\text{good},3}\rangle := \left[ |\psi_{2i-1}^{\text{good},3}\rangle \right]_1$ . Define  $|\psi_{2i-1}^{\text{bad},3}\rangle$  and  $|\phi_{2i-1}^{\text{bad},3}\rangle$  by  $|\psi_{2i-1}^{\text{bad},3}\rangle := \text{RstOE}_f^* \text{RstOE}_g \text{RstOE}_f |\psi_{2i-1}\rangle - |\psi_{2i-1}^{\text{good},3}\rangle$  and  $|\phi_{2i-1}^{\text{bad},3}\rangle := \text{RstOE}_f^* \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},3}\rangle$ .

*Remark 9.* The intuition behind the definition of  $|\psi_{2i-1}^{\text{good},3}\rangle$  is as follows. Roughly speaking, we defined  $|\psi_{2i-1}^{\text{good},3}\rangle$  in such a way that  $\Pi_{\text{pre-good}} \text{RstOE}_f |\psi_{2i-1}^{\text{good},3}\rangle$  will be close to  $|\psi_{2i-1}^{\text{good},2}\rangle$ . Suppose we have  $|\psi_{2i-1}^{\text{good},3}\rangle$  that satisfies (64) and let  $\text{RstOE}_f$  act on it (rather than we have  $|\psi_{2i-1}^{\text{good},2}\rangle$  and let  $\text{RstOE}_f^*$  act on it). Then, since this  $\text{RstOE}_f$  writes outputs into an auxiliary register, the behavior of  $\text{RstOE}_f$  is close to the classical lazy sampling. Intuitively, the followings will hold if  $\Pi_{\text{pre-good}} \text{RstOE}_f |\psi_{2i-1}^{\text{good},3}\rangle = |\psi_{2i-1}^{\text{good},2}\rangle$ .

1. Databases  $|D_f, D_g, D_h\rangle$  with  $D_f(u) \neq \perp$  are not changed by  $\text{RstOE}_f$ , and (65) holds.
2. Databases  $|D_f, D_g, D_h\rangle$  with  $D_f(u) = \perp$  are changed to  $\sum_{\alpha} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \alpha), D_g, D_h\rangle$  by  $\text{RstOE}_f$ , and (66) holds.

This is the reason that we defined  $a_{uvwxyzD_fD_gD_h}^{(2i-1),3}$  and  $|\psi_{2i-1}^{\text{good},3}\rangle$  like above. We provided definitions based on  $|\psi_{2i-1}^{\text{good},3}\rangle$  rather than  $|\psi_{2i-1}^{\text{good},2}\rangle$ , unlike previous lemmas, because it makes the proof for property 4-(b) simple (or just trivial). We defined  $|\psi_{2i-1}^{\text{bad},3}\rangle$ ,  $|\phi_{2i-1}^{\text{good},3}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},3}\rangle$  in such a way that property 1-5 of the lemma will be satisfied.

Then, property 1, 2, 3, 4-(a), and 5 of Lemma 14 immediately follow from the definitions of  $|\psi_{2i-1}^{\text{good},3}\rangle$ ,  $|\psi_{2i-1}^{\text{good},3}\rangle$ ,  $|\phi_{2i-1}^{\text{bad},3}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},3}\rangle$ . In addition, property 4-(b) of Lemma 14 follows from the definition of the coefficients  $a_{uvwxyzD_fD_gD_h}^{(2i-1),3}$  and property 4-(b) of Lemma 13. Below we show that property 6 of Lemma 14 holds.

*Remark 10.* Later, we will show that  $\left\| |\phi_{2i-1}^{\text{bad},3}\rangle \right\|$  is upper bounded by  $\left\| |\phi_{2i-1}^{\text{bad},2}\rangle \right\| + \left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\|$ . In what follows, our main goal is to show that  $\left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\|$  is in  $O(\sqrt{i/2^n})$ .

By applying the first property of Proposition 3, and by definition of regular states<sup>26</sup>, we have

$$\begin{aligned} & \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{good}} |\phi_{2i-1}^{\text{good},2}\rangle \\ &= \Pi_{\text{reg}} \text{RstOE}_f \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \\ & \quad \otimes |D_f \cup (u,\alpha), D_g \star D_h\rangle \otimes |\alpha\rangle \end{aligned} \quad (68)$$

$$= \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u,\alpha), D_g \star D_h\rangle \quad (68)$$

$$+ \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u,\gamma)\rangle \right) |D_g \star D_h\rangle \quad (69)$$

$$- \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{2^n} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \otimes |D_f \cup (u,\alpha), D_g \star D_h\rangle \quad (70)$$

$$+ \frac{1}{2^{3n/2}} \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \otimes \left( 2 \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u,\gamma)\rangle - |D_f\rangle \right) |D_g \star D_h\rangle, \quad (71)$$

where the terms (68)-(71) correspond to (5)-(8), respectively.

On the term (68).

Let  $\Pi_{\perp}$  be the orthogonal projection onto the space spanned by the vectors  $|u,v\rangle |y\rangle |z\rangle |D_f, D_g, D_h\rangle$  such that  $D_f(u) \neq \perp$ . Then

$$|(68)\rangle = \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \quad (72)$$

holds.

<sup>26</sup> Recall that a state is regular if and only if it does not contain invalid databases and the auxiliary register is set to be 0. In particular, the projection  $\Pi_{\text{reg}}$  nullifies the terms with invalid databases and those of which auxiliary register is non-zero.

Upper bounding the norm of the terms (69) and (71).

First we have

$$\begin{aligned}
& \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle |D_f, D_g \star D_h\rangle \right\|^2 \\
&= \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h,D'_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp \\ D_g \star D_h = D'_h}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle |D_f, D'_h\rangle \right\|^2 \\
&= \sum_{\substack{u,v,y,z,D_f; \\ D_f(u)=\perp}} \frac{1}{2^n} \sum_{D'_h} \left| \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2. \tag{73}
\end{aligned}$$

For each database  $(D_f, D'_h)$  such that  $D_f(u) = \perp$  for  $F_1^h$ , the number of  $\alpha$  such that  $(D_f \cup (u, \alpha), D'_h)$  becomes good is at most  $|D'_h| \leq O(i)$ . Hence we can show

$$\begin{aligned}
& \sum_{D'_h} \left| \sum_{\substack{\alpha,D_g,D_h; \\ D_g \star D_h = D'_h \\ (D_f \cup (u,\alpha), D'_h): \text{good}}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2 \\
&\leq O(i) \cdot \sum_{\substack{\alpha,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2 \tag{74}
\end{aligned}$$

in the same way as we showed (49). From (73) and (74), it follows that

$$\begin{aligned}
& \left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle |D_f, D_g \star D_h\rangle \right\|^2 \\
&\leq \sum_{\substack{u,v,y,z,D_f; \\ D_f(u)=\perp}} O\left(\frac{i}{2^n}\right) \cdot \sum_{\substack{\alpha,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good}}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2
\end{aligned}$$

$$\begin{aligned}
&= O\left(\frac{i}{2^n}\right) \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2 \\
&\leq O\left(\frac{i}{2^n}\right) \cdot \left\| |\phi_{2i-1}^{\text{good},2}\rangle \right\|^2 \leq O\left(\frac{i}{2^n}\right)
\end{aligned} \tag{75}$$

holds. We can show

$$\begin{aligned}
&\left\| \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} |u,v\rangle |y\rangle |z\rangle \right. \\
&\quad \left. \otimes \left( \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u,\gamma)\rangle \right) |D_g \star D_h\rangle \right\|^2 \\
&\leq O\left(\frac{i}{2^n}\right) \cdot \left\| |\phi_{2i-1}^{\text{good},2}\rangle \right\|^2 \leq O\left(\frac{i}{2^n}\right)
\end{aligned} \tag{76}$$

in the same way. Now,

$$\| |(69)\rangle \| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \text{ and } \| |(71)\rangle \| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \tag{77}$$

follow from (75) and (76).

Upper bounding the norm of the term (70).

We have that

$$\begin{aligned}
\| |(70)\rangle \|^2 &= \frac{1}{2^{2n}} \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_f \cup (u,\alpha)D_gD_h}^{(2i-1),2} \right|^2 \\
&\leq \frac{1}{2^{2n}} \left\| |\phi_{2i-1}^{\text{good},2}\rangle \right\|^2 \leq O\left(\frac{1}{2^{2n}}\right)
\end{aligned} \tag{78}$$

holds since all summands are orthogonal to each other.

Now, from (68) - (71), (72), (77), and (78),

$$\left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{good}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \tag{79}$$

follows.

*Remark 11.* So far we have shown  $\left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{good}} |\phi_{2i-1}^{\text{good},2}\rangle \right\|$  is small. Next we will prove  $\left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\|$  is small, which will lead to showing that  $\left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\|$  is small.

Next, let  $\Pi_{\perp}$  be the orthogonal projection onto the space spanned by the vectors  $|u, v\rangle |y\rangle |z\rangle |D_f, D_g \star D_h\rangle$  such that  $D_f(u) = \perp$ . Then, by applying the second property in Proposition 3, we have

$$\begin{aligned}
& \text{RstOE}_f \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \\
&= \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \frac{1}{\sqrt{2^n}} a_{uvyzD_fD_gD_h}^{(2i-1),3} |u, v\rangle |y\rangle |z\rangle \\
&\quad \otimes |D_f \cup (u, \alpha), D_g \star D_h\rangle \otimes |\alpha\rangle \\
&+ \frac{1}{\sqrt{2^n}} \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_fD_gD_h}^{(2i-1),3} |u, v\rangle |y\rangle |z\rangle \\
&\quad \otimes \left( |D_f\rangle - \sum_{\gamma} \frac{1}{\sqrt{2^n}} |D_f \cup (u, \gamma)\rangle \right) |D_g \star D_h\rangle \otimes |\widehat{0^n}\rangle,
\end{aligned} \tag{80}$$

$$\tag{81}$$

where the terms (80) and (81) correspond to (9) and (10), respectively.

On the term  $\Pi_{\text{pre-good}} |(80)\rangle$ .

By the equation (65),

$$\Pi_{\text{pre-good}} |(80)\rangle = \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \tag{82}$$

holds.<sup>27</sup>

Upper bounding the norms of the terms  $\Pi_{\text{pre-bad}} |(80)\rangle$  and  $|(81)\rangle$ .

For a good database  $(D_f, D_g, D_h)$  for  $F_2$ , let  $\text{NumPreGood}(D_f, D_g, D_h)$  be the number of  $\alpha$  such that  $(D_f \cup (u, \alpha), D_g, D_h)$  becomes pre-good. Then we have  $|\text{NumPreGood}(D_f, D_g, D_h)| \geq 2^n - |D_f| - |D_h| \geq 2^n - 2i$ , and

$$\begin{aligned}
& \left| a_{uvyzD_fD_gD_h}^{(2i-1),3} \right| \\
&= \left| \frac{\sqrt{2^n}}{\text{NumPreGood}(D_f, D_g, D_h)} \sum_{\substack{\alpha; \\ (D_f \cup (u, \alpha), D_g, D_h): \text{pre-good}}} a_{uvyzD_f \cup (u, \alpha) D_g D_h}^{(2i-1),2} \right| \\
&\leq \left| \frac{\sqrt{2^n}}{2^n - 2i} \sum_{\substack{\alpha; \\ (D_f \cup (u, \alpha), D_g, D_h): \text{pre-good}}} a_{uvyzD_f \cup (u, \alpha) D_g D_h}^{(2i-1),2} \right|
\end{aligned} \tag{83}$$

holds. Thus we have that

$$\left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \right\|^2$$

<sup>27</sup> Note that here we are focusing on *pre-good and bad* databases. See also Remark 5.

$$\begin{aligned}
&= \left\| \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} a_{uvyzD_fD_gD_h}^{(2i-1),3} |u,v\rangle |y\rangle |z\rangle \otimes |D_f, D_g \star D_h\rangle \right\|^2 \\
&= \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left| a_{uvyzD_fD_gD_h}^{(2i-1),3} \right|^2 \\
&\stackrel{(83)}{\leq} \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left| \frac{\sqrt{2^n}}{2^n - 2i} \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-good}}} a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1),2} \right|^2 \\
&= \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left( \frac{\sqrt{2^n}}{2^n - 2i} \right)^2 \left| \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-good}}} a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1),2} \right|^2 \\
&\leq \sum_{\substack{u,v,y,z,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp}} \left( \frac{\sqrt{2^n}}{2^n - 2i} \right)^2 \cdot 2^n \sum_{\substack{\alpha; \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-good}}} \left| a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1),2} \right|^2 \\
&= O(1) \cdot \sum_{\substack{u,v,y,z,\alpha,D_f,D_g,D_h; \\ (D_f,D_g,D_h): \text{good} \\ D_f(u)=\perp \\ (D_f \cup (u,\alpha), D_g, D_h): \text{pre-good}}} \left| a_{uvyzD_f \cup (u,\alpha) D_g D_h}^{(2i-1),2} \right|^2 \\
&\leq O(1) \cdot \left\| \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\|^2 \tag{84}
\end{aligned}$$

holds, where ‘‘convexity’’ denotes convexity of square functions. <sup>28</sup> Therefore

$$\left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \right\| \leq \left\| \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \cdot O(1) \leq O(1) \tag{85}$$

holds.

Since (85) holds, we can show

$$\left\| \Pi_{\text{pre-bad}} |(80)\rangle \right\| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \cdot \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \right\| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \tag{86}$$

and

$$\left\| |(81)\rangle \right\| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \cdot \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle \right\| \leq O\left(\sqrt{\frac{i}{2^n}}\right) \tag{87}$$

<sup>28</sup> Note that  $\Pi_{\text{bad}}$  do not cancel pre-good and bad databases.

in the same way as we showed (52) and (53) in the proof of Lemma 11, respectively.

Now it follows that

$$\begin{aligned}
& \left\| \text{RstOE}_f \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&= \left\| (|(80)\rangle + |(81)\rangle) - \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&= \left\| \Pi_{\text{pre-good}} |(80)\rangle + \Pi_{\text{pre-bad}} |(80)\rangle + |(81)\rangle - \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&\stackrel{(82)}{=} \left\| \Pi_{\text{pre-bad}} |(80)\rangle + |(81)\rangle \right\| \\
&\stackrel{(86) \text{ and } (87)}{\leq} O\left(\sqrt{\frac{i}{2^n}}\right) \tag{88}
\end{aligned}$$

holds.

Since  $\Pi_{\text{reg}} \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle = \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle$  holds by definition of  $|\phi_{2i-1}^{\text{good},3}\rangle$ ,

$$\begin{aligned}
& \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&= \left\| \Pi_{\text{reg}} \left( \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \text{RstOE}_f^* \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right) \right\| \\
&\leq \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \text{RstOE}_f^* \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&\stackrel{(88)}{\leq} O\left(\sqrt{\frac{i}{2^n}}\right) \tag{89}
\end{aligned}$$

holds.

From (79) and (89), it follows that

$$\begin{aligned}
& \left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&\leq \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{good}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&\quad + \left\| \Pi_{\perp} |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* \Pi_{\text{bad}} |\phi_{2i-1}^{\text{good},2}\rangle \right\| \\
&\leq O\left(\sqrt{\frac{i}{2^n}}\right) \tag{90}
\end{aligned}$$

holds.

Since we obtain a regular database whenever we measure the state  $\text{RstOE}_f^* \text{RstOE}_h \cdot \text{RstOE}_f |\phi_{2i-1}\rangle$ ,

$$\Pi_{\text{reg}} \text{RstOE}_f^* \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle = \text{RstOE}_f^* \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle \tag{91}$$

holds. Therefore, from property 1 and 6 in Lemma 13, (90), and (91),

$$\left\| |\phi_{2i-1}^{\text{bad},3}\rangle \right\|$$

$$\begin{aligned}
&= \left\| \text{RstOE}_f^* \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},3}\rangle \right\| \\
&\stackrel{(91)}{=} \left\| \Pi_{\text{reg}} \text{RstOE}_f^* \text{RstOE}_h \text{RstOE}_f |\phi_{2i-1}\rangle - |\phi_{2i-1}^{\text{good},3}\rangle \right\| \\
&\stackrel{\text{property 1}}{=} \left\| \Pi_{\text{reg}} \text{RstOE}_f^* \left( |\phi_{2i-1}^{\text{good},2}\rangle + |\phi_{2i-1}^{\text{bad},2}\rangle \right) - |\phi_{2i-1}^{\text{good},3}\rangle \right\| \\
&\leq \left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\| + \left\| |\phi_{2i-1}^{\text{bad},2}\rangle \right\| \\
&\stackrel{\text{property 6}}{\leq} \left\| |\phi_{2i-1}^{\text{good},3}\rangle - \Pi_{\text{reg}} \text{RstOE}_f^* |\phi_{2i-1}^{\text{good},2}\rangle \right\| + \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| + O\left(\sqrt{\frac{i}{2^n}}\right) \\
&\stackrel{(90)}{\leq} O\left(\sqrt{\frac{i}{2^n}}\right) + \left\| |\phi_{2i-1}^{\text{bad}}\rangle \right\| \tag{92}
\end{aligned}$$

follows, which implies that property 6 of Lemma 14 for  $|\phi_{2i-1}^{\text{bad},3}\rangle$  holds. We can show property 6 of the lemma for  $|\psi_{2i-1}^{\text{bad},3}\rangle$  in the same way.  $\square$

*Proof (of Proposition 5).* We show the claim by induction on  $j$ . The claim for  $j = 1$  obviously holds by setting  $|\phi_1^{\text{good}}\rangle = |\phi_1\rangle$ ,  $|\psi_1^{\text{good}}\rangle = |\psi_1\rangle$ ,  $|\phi_1^{\text{bad}}\rangle = 0$ , and  $|\psi_1^{\text{bad}}\rangle = 0$ .

From  $(2i-1)$  to  $2i$ . Here we show that the claim holds for  $j = 2i$  if the claim holds for  $j = 1, \dots, 2i-1$ . By Lemma 14, there exist vectors  $|\psi_{2i-1}^{\text{good},3}\rangle$ ,  $|\psi_{2i-1}^{\text{bad},3}\rangle$ ,  $|\phi_{2i-1}^{\text{good},3}\rangle$ , and  $|\phi_{2i-1}^{\text{bad},3}\rangle$  that satisfy the six properties in Lemma 14.

Let  $U_{2i-1}$  denote the unitary operator that corresponds to the offline computation by  $\mathcal{A}$  between the  $(2i-1)$ -th query (the  $i$ -th query to  $F_1^h$  or  $F_2$ ) and the  $2i$ -th query (the  $i$ -th query to  $h$ ), and define

$$\begin{aligned}
|\psi_{2i}^{\text{good}}\rangle &:= U_{2i-1} |\psi_{2i-1}^{\text{good},3}\rangle, & |\psi_{2i}^{\text{bad}}\rangle &= U_{2i-1} |\psi_{2i-1}^{\text{bad},3}\rangle, \\
|\phi_{2i}^{\text{good}}\rangle &:= U_{2i-1} |\phi_{2i-1}^{\text{good},3}\rangle, & |\phi_{2i}^{\text{bad}}\rangle &= U_{2i-1} |\phi_{2i-1}^{\text{bad},3}\rangle.
\end{aligned}$$

Then, the six properties in Proposition 5 for  $j = 2i$  immediately follow from the six properties in Lemma 14. Hence the claim holds for  $j = 2i$ .

From  $2i$  to  $2i+1$ . Here we show that the claim holds for  $j = 2i+1$  if the claim holds for  $j = 1, \dots, 2i$ . Let  $\Pi_{\text{hit}}$  be the orthogonal projection onto the space that is spanned by the vectors  $|v, \zeta\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle$  (or,  $|v, \zeta\rangle |y\rangle |z\rangle \otimes |D_f, D_h\rangle$ ) such that  $(u, \zeta) \in D_f$  for some  $u$ <sup>29</sup>. In addition, let  $\Pi_{\text{-hit}} := I - \Pi_{\text{hit}}$ .

Let  $U_{2i}$  denote the unitary operator that corresponds to the offline computation by  $\mathcal{A}$  between the  $2i$ -th query (the  $i$ -th query to  $h$ ) and the  $(2i+1)$ -st query (the  $(i+1)$ -st query to  $F_1^h$  or  $F_2$ ). We define  $|\psi_{2i}^{\text{good}}\rangle$ ,  $|\psi_{2i}^{\text{bad}}\rangle$ ,  $|\phi_{2i}^{\text{good}}\rangle$ , and  $|\phi_{2i}^{\text{bad}}\rangle$  by  $|\psi_{2i+1}^{\text{good}}\rangle := U_{2i} \Pi_{\text{valid}} \text{RstOE}_h \Pi_{\text{-hit}} |\psi_{2i}^{\text{good}}\rangle$ ,  $|\psi_{2i+1}^{\text{bad}}\rangle := |\psi_{2i+1}\rangle - |\psi_{2i+1}^{\text{good}}\rangle$ ,  $|\phi_{2i+1}^{\text{good}}\rangle := U_{2i} \Pi_{\text{valid}} \text{RstOE}_h \Pi_{\text{-hit}} |\phi_{2i}^{\text{good}}\rangle$ ,  $|\phi_{2i+1}^{\text{bad}}\rangle := |\phi_{2i+1}\rangle - |\phi_{2i+1}^{\text{good}}\rangle$ .

<sup>29</sup> This projection corresponds to the event hit in Section 1.2.

Then property 1 of Proposition 5 for  $j = 2i + 1$  holds by definition of  $|\psi_{2i}^{\text{good}}\rangle$ ,  $|\psi_{2i}^{\text{bad}}\rangle$ ,  $|\phi_{2i}^{\text{good}}\rangle$ , and  $|\phi_{2i}^{\text{bad}}\rangle$ . Property 2, 3, 4, 5 for  $j = 2i + 1$  can be shown by checking how the coefficients of basis vectors in  $\Pi_{\text{-hit}}|\psi_{2i}^{\text{good}}\rangle$  and  $\Pi_{\text{-hit}}|\phi_{2i}^{\text{good}}\rangle$  change when  $\text{RstOE}_h$  act on them (by applying Proposition 3 on  $\text{RstOE}_h$ ).<sup>30</sup>

Below we show that property 6 holds for  $j = 2i + 1$ .

For a good database  $(D_f, D_g, D_h)$  for  $F_2$ , let  $\text{Equiv}(D_f, D_g, D_h)$  be the set of good databases that are equivalent to  $(D_f, D_g, D_h)$ . Let  $\mathbb{R}$  be a complete system of representatives of the equivalence relation on good databases for  $F_2$  (i.e.,  $\mathbb{R}$  is a set of good databases for  $F_2$  such that the set of all good databases for  $F_2$  is decomposed into the disjoint union  $\coprod_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \text{Equiv}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)$ ). In addition, for a good database  $(D_f, D_g, D_h)$  for  $F_2$  and  $\zeta$ , let  $\text{EquivHit}_\zeta(D_f, D_g, D_h)$  be the set of good databases  $(D'_f, D'_g, D'_h)$  such that  $(D'_f, D'_g, D'_h)$  is equivalent to  $(D_f, D_g, D_h)$  and  $(u, \zeta) \in D'_f$  for some  $u$ . Then the following claim holds.

*Claim.* For each  $\zeta$  and each good database  $(D_f, D_g, D_h) \in \mathbb{R}$  such that  $a_{v\zeta yz D_f D_g D_h}^{(2i)} \neq 0$  for some  $v, \zeta, y, z$ ,

$$\frac{|\text{EquivHit}_\zeta(D_f, D_g, D_h)|}{|\text{Equiv}(D_f, D_g, D_h)|} \leq O\left(\frac{i}{2^n}\right)$$

holds.<sup>31</sup>

*Proof.* Let

$$S := \{\zeta' \in \{0, 1\}^n \mid \exists v, w \text{ s.t. } ((v, \zeta'), w) \in D_h\},$$

and

$$\Pi_S := \{\pi : \{0, 1\}^n \rightarrow \{0, 1\}^n \mid \pi \text{ is a permutation and } \pi(\zeta') = \zeta' \text{ for all } \zeta' \in S\}.$$

Then, a good database  $(D'_f, D'_g, D'_h)$  is equivalent to  $(D_f, D_g, D_h)$  if and only if there exists  $\pi \in \Pi_S$  such that

1.  $D'_h = D'_h$ ,
2.  $(u, \zeta') \in D'_f$  if and only if  $(u, \pi(\zeta')) \in D_f$ , and
3.  $((u, v, \zeta'), w) \in D'_g$  if and only if  $((u, v, \pi(\zeta')), w) \in D_g$  holds.

Therefore we have

$$\frac{|\text{EquivHit}_\zeta(D_f, D_g, D_h)|}{|\text{Equiv}(D_f, D_g, D_h)|} = \Pr_{\pi \leftarrow \Pi_S} [\text{There exists } (u, \zeta') \in D_f \text{ such that } \pi(\zeta') = \zeta].$$

<sup>30</sup> Intuitively, the behavior of  $\text{RstOE}_h$  on  $\Pi_{\text{-hit}}|\psi_{2i}^{\text{good}}\rangle$  is the same as that of  $\text{RstOE}_h$  on  $\Pi_{\text{-hit}}|\phi_{2i}^{\text{good}}\rangle$ .

<sup>31</sup> In (14) we used the symbol  $a_{uvyz D_f D_g D_h}^{(2i)}$  for ease of notations, but here we use  $a_{v\zeta yz D_f D_g D_h}^{(2i)}$  (“ $uv$ ” is replaced with “ $v\zeta$ ”) because we use the symbol  $v|\zeta$  to denote an input to  $h$ .

The probability on the right hand side is upper bounded as

$$\begin{aligned}
& \Pr_{\pi \stackrel{\$}{\leftarrow} \Pi_S} [\text{There exists } (u, \zeta') \in D_f \text{ such that } \pi(\zeta') = \zeta] \\
& \leq \sum_{(u, \zeta') \in D_f} \Pr_{\pi \stackrel{\$}{\leftarrow} \Pi_S} [\pi(\zeta') = \zeta] = \sum_{(u, \zeta') \in D_f} \frac{|\{\pi \in \Pi_S | \pi(\zeta') = \zeta\}|}{|\Pi_S|} \\
& = \sum_{(u, \zeta') \in D_f} \frac{(2^n - |S| - 1)!}{(2^n - |S|)!} = \frac{|D_f|}{2^n - |D_h|} \leq O\left(\frac{i}{2^n}\right).
\end{aligned}$$

Hence the claim follows.  $\square$

Now we have

$$\begin{aligned}
\left\| \Pi_{\text{hit}} |\psi_{2i}^{\text{good}}\rangle \right\|^2 &= \left\| \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h): \text{good} \\ \exists u \text{ s.t. } (u, \zeta) \in D_f}} a_{v\zeta yz D_f D_g D_h}^{(2i)} |v, \zeta\rangle |y\rangle |z\rangle \otimes |D_f, D_g, D_h\rangle \right\|^2 \\
&= \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h): \text{good} \\ \exists u \text{ s.t. } (u, \zeta) \in D_f}} \left| a_{v\zeta yz D_f D_g D_h}^{(2i)} \right|^2 \\
&= \sum_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h) \in \text{Equiv}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \\ \exists u \text{ s.t. } (u, \zeta) \in \tilde{D}_f}} \left| a_{v\zeta yz D_f D_g D_h}^{(2i)} \right|^2 \\
&\stackrel{\text{property 4}}{=} \sum_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h) \in \text{Equiv}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \\ \exists u \text{ s.t. } (u, \zeta) \in \tilde{D}_f}} \left| a_{v\zeta yz \tilde{D}_f \tilde{D}_g \tilde{D}_h}^{(2i)} \right|^2 \\
&= \sum_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \sum_{v, \zeta, y, z} \left| \text{EquivHit}_{\zeta}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \right| \left| a_{v\zeta yz \tilde{D}_f \tilde{D}_g \tilde{D}_h}^{(2i)} \right|^2 \\
&\stackrel{(\text{Claim})}{\leq} O\left(\frac{i}{2^n}\right) \cdot \sum_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \sum_{v, \zeta, y, z} \left| \text{Equiv}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \right| \left| a_{v\zeta yz \tilde{D}_f \tilde{D}_g \tilde{D}_h}^{(2i)} \right|^2 \\
&\stackrel{\text{property 4}}{=} O\left(\frac{i}{2^n}\right) \cdot \sum_{(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h) \in \mathbb{R}} \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h) \in \text{Equiv}(\tilde{D}_f, \tilde{D}_g, \tilde{D}_h)}} \left| a_{v\zeta yz D_f D_g D_h}^{(2i)} \right|^2 \\
&= O\left(\frac{i}{2^n}\right) \cdot \sum_{\substack{v, \zeta, y, z, D_f, D_g, D_h; \\ (D_f, D_g, D_h): \text{good}}} \left| a_{v\zeta yz D_f D_g D_h}^{(2i)} \right|^2
\end{aligned}$$

$$= O\left(\frac{i}{2^n}\right) \cdot \left\| |\psi_{2i}^{\text{good}}\rangle \right\|^2 \leq O\left(\frac{i}{2^n}\right). \quad (93)$$

Therefore we have

$$\begin{aligned} \left\| |\psi_{2i+1}^{\text{bad}}\rangle \right\| &= \left\| |\psi_{2i+1}\rangle - |\psi_{2i+1}^{\text{good}}\rangle \right\| \\ &= \left\| U_{2i} \text{RstOE}_h |\psi_{2i}\rangle - U_{2i} \Pi_{\text{valid}} \text{RstOE}_h \Pi_{\text{-hit}} |\psi_{2i}^{\text{good}}\rangle \right\| \\ &= \left\| \Pi_{\text{valid}} \text{RstOE}_h |\psi_{2i}\rangle - \Pi_{\text{valid}} \text{RstOE}_h \Pi_{\text{-hit}} |\psi_{2i}^{\text{good}}\rangle \right\| \\ &\leq \left\| |\psi_{2i}\rangle - \Pi_{\text{-hit}} |\psi_{2i}^{\text{good}}\rangle \right\| = \left\| |\psi_{2i}^{\text{good}}\rangle + |\psi_{2i}^{\text{bad}}\rangle - \Pi_{\text{-hit}} |\psi_{2i}^{\text{good}}\rangle \right\| \\ &\leq \left\| |\psi_{2i}^{\text{bad}}\rangle \right\| + \left\| \Pi_{\text{hit}} |\psi_{2i}^{\text{good}}\rangle \right\| \leq \left\| |\psi_{2i}^{\text{bad}}\rangle \right\| + O\left(\sqrt{\frac{i}{2^n}}\right), \end{aligned}$$

where we used the fact that we always obtain a valid database when we measure the state  $\text{RstOE}_h |\psi_{2i}\rangle$ , for the third equality. Hence the sixth property for  $|\psi_{2i+1}^{\text{bad}}\rangle$  holds. We can show that the sixth property for  $|\psi_{2i+1}^{\text{bad}}\rangle$  holds in the same way.  $\square$

## D Proof of Lemma 4

*Proof (of Lemma 4).* Recall that each message for NMAC is first processed with  $\text{MD}^h(K_1, \cdot)$ <sup>32</sup> and second with  $\text{MD}^h(K_2, \cdot)$ . In addition, the length of messages processed with  $\text{MD}^h(K_2, \cdot)$  is fixed to be  $n$ . Let  $\overline{\text{MD}}^h(K_2, \cdot) : \{0, 1\}^n \rightarrow \{0, 1\}^n$  be the function that is the same as  $\text{MD}^h(K_2, \cdot)$  but the domain is restricted to  $\{0, 1\}^n$ . Recall that we call  $\text{MD}^h(K_1, \cdot)$  and  $\overline{\text{MD}}^h(K_2, \cdot)$  the inner function and the outer function, respectively. Then, the difference between  $\text{NMAC}_{K_1, K_2}^h$  and the function  $H_1^h$  in  $G_1$  are: (i) The first application of  $h$  in the inner function in  $\text{NMAC}_{K_1, K_2}^h$  (i.e., the function  $h(\cdot \| K_1)$ ) is replaced with a random function  $f_1$  in  $H_1^h$ . (ii) The outer function in  $\text{NMAC}_{K_1, K_2}^h$  is replaced with a random function  $f_{\text{out}}$  in  $H_1^h$ .

Let  $\tilde{H}_1^h$  be the function that is the same as  $H_1^h$  except that the random function  $f_1$  is replaced with  $h(\cdot \| K_1)$  ( $K_1 \in \{0, 1\}^n$  is chosen uniformly at random). Then, for a quantum adversary  $\mathcal{A}$  to distinguish  $(\text{NMAC}_{K_1, K_2}^h, h)$  from  $(\tilde{H}_1^h, h)$  that makes at most  $Q$  quantum queries to  $\text{NMAC}_{K_1, K_2}^h$  or  $\tilde{H}_1^h$  and at most  $q_h$  quantum queries to  $h$ , we can construct another adversary  $\mathcal{B}$  to distinguish  $(\overline{\text{MD}}^h(K_2, \cdot), h)$  from  $(f_{\text{out}}, h)$  that makes at most  $O(Q)$  queries to  $\overline{\text{MD}}^h(K_2, \cdot)$  or  $f_{\text{out}}$  and at most  $O(q_h + Q\ell)$  quantum queries to  $h$  as follows.

$\mathcal{B}$  is given quantum oracle access to  $\mathcal{O}^h$  ( $\mathcal{O}^h = \overline{\text{MD}}^h(K_2, \cdot)$  or  $\mathcal{O}^h = f_{\text{out}}$ ) and  $h$ . First,  $\mathcal{B}$  chooses  $K_1 \in \{0, 1\}^n$  uniformly at random, and runs  $\mathcal{A}$ . When  $\mathcal{A}$  makes a query to the second oracle (which is supposed to be  $h$ ),  $\mathcal{B}$  responds by

<sup>32</sup> Remember that the definition of  $\text{NMAC}_{K_1, K_2}^h$  is slightly modified during the proof of Proposition 6.

querying to  $h$ . When  $\mathcal{A}$  queries a message  $M$  to the first oracle (which is supposed to be  $\text{NMAC}_{K_1, K_2}^h$  or  $\tilde{H}_1^h$ ),  $\mathcal{B}$  computes the value  $T := \mathcal{O}^h(\text{MD}^h(K_1, M))$  by making queries to  $\mathcal{O}^h$  and  $h$ , and responds to  $\mathcal{A}$  with  $T$ . Finally  $\mathcal{B}$  returns  $\mathcal{A}$ 's output as its own output.

Then  $\mathcal{B}$  makes at most  $O(Q)$  queries to  $\mathcal{O}^h$  and at most  $O(q_h + Q\ell)$  queries to  $h$ . In addition,  $\mathcal{B}$  completely simulates  $\text{NMAC}_{K_1, K_2}^h$  or  $\tilde{H}_1$  depending on  $\mathcal{O}^h = \overline{\text{MD}}^h(K_2, \cdot)$  or  $\mathcal{O}^h = f_{out}$ . Thus

$$\text{Adv}_{(\text{NMAC}_{K_1, K_2}^h, h), (\tilde{H}_1^h, h)}^{\text{dist}}(\mathcal{A}) = \text{Adv}_{(\overline{\text{MD}}^h(K_2, \cdot), h), (f_{out}, h)}^{\text{dist}}(\mathcal{B}) = \text{Adv}_{\overline{\text{MD}}^h(K_2, \cdot)}^{\text{qPRF}}(\mathcal{B}) \quad (94)$$

holds.

Below we consider two cases depending on whether  $|\text{pad}(M)| = m$  or  $|\text{pad}(M)| \geq m$  for  $M \in \{0, 1\}^n$ .

*Proof for the case that  $|\text{pad}(M)| = m$  for  $M \in \{0, 1\}^n$ .*

In this case,  $\overline{\text{MD}}^h(K_2, M) = h(\text{pad}(M) || K_2)$  holds for all  $M \in \{0, 1\}^n$ . Thus, from Lemma 1,

$$\text{Adv}_{\overline{\text{MD}}^h(K_2, \cdot)}^{\text{qPRF}}(\mathcal{B}) = \text{Adv}_{h(\text{pad}(\cdot) || K_2)}^{\text{qPRF}}(\mathcal{B}) \leq O\left(\frac{q_h + Q\ell}{2^{n/2}}\right) \quad (95)$$

follows. From (94) and (95),

$$\text{Adv}_{(\text{NMAC}_{K_1, K_2}^h, h), (\tilde{H}_1^h, h)}^{\text{dist}}(\mathcal{A}) \leq O\left(\frac{q_h + Q\ell}{2^{n/2}}\right) \quad (96)$$

holds.

In the same way as we showed (96), we can show that

$$\text{Adv}_{(\tilde{H}_1^h, h), (H_1^h, h)}^{\text{dist}}(\mathcal{A}) \leq O\left(\frac{q_h + Q\ell}{2^{n/2}}\right) \quad (97)$$

holds (that is, we can replace  $h(\cdot || K_1)$  in the inner function of  $\tilde{H}_1^h$  with the random function  $f_1$ ). Hence

$$\text{Adv}_{(\text{NMAC}_{K_1, K_2}^h, h), (H_1^h, h)}^{\text{dist}}(\mathcal{A}) \leq O\left(\frac{q_h + Q\ell}{2^{n/2}}\right) \quad (98)$$

follows from (96) and (97).

*Proof for the case that  $|\text{pad}(M)| = m \cdot j$  ( $j > 1$ ) for  $M \in \{0, 1\}^n$ .*

We show the claim for the case that  $|\text{pad}(M)| = 2m$  for  $M \in \{0, 1\}^n$ . Other cases can be shown in the same way.

Let  $\hat{f}_{out} : \{0, 1\}^m \times \{0, 1\}^m \rightarrow \{0, 1\}^n$  be the function defined by  $\hat{f}_{out}(u, v) := h(v || \rho(u))$ , where  $\rho : \{0, 1\}^m \rightarrow \{0, 1\}^n$  is a random function. Let  $f_{big} : \{0, 1\}^m \times \{0, 1\}^m \rightarrow \{0, 1\}^n$  be another random function.

Now,

$$\mathbf{Adv}_{(\overline{\text{MD}}^h(K_2, \cdot), h), (\hat{f}_{out} \circ \text{pad}, h)}^{\text{dist}}(\mathcal{B}) \leq O\left(\frac{q_h + Q\ell}{2^{n/2}}\right) \quad (99)$$

follows from Lemma 1<sup>33</sup>, and

$$\mathbf{Adv}_{(\hat{f}_{out} \circ \text{pad}, h), (f_{big} \circ \text{pad}, h)}^{\text{dist}}(\mathcal{B}) \leq O\left(\sqrt{\frac{(q_h + Q\ell)^3}{2^n}}\right) \quad (100)$$

follows from Proposition 4. In addition,

$$\mathbf{Adv}_{(\hat{f}_{out} \circ \text{pad}, h), (f_{big} \circ \text{pad}, h)}^{\text{dist}}(\mathcal{B}) = \mathbf{Adv}_{(\hat{f}_{out} \circ \text{pad}, h), (f_{out}, h)}^{\text{dist}}(\mathcal{B}) \quad (101)$$

holds since  $\text{pad} : M \mapsto \text{pad}(M)$  is injective for  $M \in \{0, 1\}^n$  and  $f_{big}$  is a random function. From (99), (100), and (101),

$$\mathbf{Adv}_{\overline{\text{MD}}^h(K_2, \cdot)}^{\text{qPRF}}(\mathcal{B}) = \mathbf{Adv}_{(\overline{\text{MD}}^h(K_2, \cdot), h), (f_{out}, h)}^{\text{dist}}(\mathcal{B}) \leq O\left(\sqrt{\frac{(q_h + Q\ell)^3}{2^n}}\right) \quad (102)$$

follows.

Since (97) also holds when  $|\text{pad}(M)| > m$  for  $M \in \{0, 1\}^n$ ,

$$\mathbf{Adv}_{(\text{NMAC}_{K_1, K_2}^h, h), (H_1^h, h)}^{\text{dist}}(\mathcal{A}) \leq O\left(\sqrt{\frac{(q_h + Q\ell)^3}{2^n}}\right) \quad (103)$$

follows from (94), (97), and (102).  $\square$

## E Proof of Lemma 5

*Proof (of Lemma 5).* Let  $\widehat{\text{NMAC}}_{K_1, K_2}^h$  be the function that is defined in the same way as  $\text{NMAC}_{K_1, K_2}^h$  but the outer function  $\text{MD}^h(K_2, \cdot)$  is replaced with the function  $\text{MD}''^h(K_2, \cdot)$ , where  $\text{MD}''^h : \{0, 1\}^n \times \{0, 1\}^* \rightarrow \{0, 1\}^n$  is defined in the same way as  $\text{MD}^h$  but the padding function is replaced from  $\text{pad}$  to  $\text{pad}''$ , which is defined by  $\text{pad}''(M) = M \parallel_{\text{p}}(|M| + m)$ . Then we have

$$\begin{aligned} & \mathbf{Adv}_{(\text{HMAC}_K^h, h), (H_1^h, h)}^{\text{dist}}(\mathcal{A}) \\ & \leq \mathbf{Adv}_{(\text{HMAC}_K^h, h), (\widehat{\text{NMAC}}_{K_1, K_2}^h, h)}^{\text{dist}}(\mathcal{A}) + \mathbf{Adv}_{(\widehat{\text{NMAC}}_{K_1, K_2}^h, h), (H_1^h, h)}^{\text{dist}}(\mathcal{A}), \end{aligned} \quad (104)$$

and we can show

$$\mathbf{Adv}_{(\widehat{\text{NMAC}}_{K_1, K_2}^h, h), (F_1^h, h)}^{\text{dist}}(\mathcal{A})$$

<sup>33</sup> The difference between  $\overline{\text{MD}}^h(K_2, \cdot)$  and  $\hat{f}_{out} \circ \text{pad}$  is that  $h(\cdot \parallel K_2)$  in the former is replaced with  $\rho$  in the latter.

$$\leq \begin{cases} O\left(\sqrt{\frac{q_h + Q\ell}{2^{n/2}}}\right) & \text{if } |\mathbf{p}(m+n)| = 2m, \\ O\left(\sqrt{\frac{(q_h + Q\ell)^3}{2^n}}\right) & \text{if } |\mathbf{p}(n+m)| = m \cdot j \ (j > 2), \end{cases} \quad (105)$$

in the same way as we proved Lemma 4.

Upper bounding the term  $\mathbf{Adv}_{(\text{HMAC}_K^h, h), (\widehat{\text{NMAC}}_{K_1, K_2}^h, h)}^{\text{dist}}(\mathcal{A})$ .

Let  $\rho^h : \{0, 1\}^k \rightarrow \{0, 1\}^{2n}$  be the function defined by

$$\rho^h(K) := h((K \| 0^{m-k} \oplus \text{ipad}) \| IV) \| h((K \| 0^{m-k} \oplus \text{opad}) \| IV). \quad (106)$$

For a quantum adversary  $\mathcal{A}$  to distinguish  $(\text{HMAC}_K^h, h)$  from  $(\widehat{\text{NMAC}}_{K_1, K_2}^h, h)$  that makes at most  $Q$  quantum queries to  $\text{HMAC}_K^h$  or  $\widehat{\text{NMAC}}_{K_1, K_2}^h$  and at most  $q_h$  quantum queries to  $h$ , we construct another adversary  $\mathcal{B}$  to distinguish the bit string  $\rho^h(K)$  ( $K$  is chosen uniformly at random) from a truly random  $2n$ -bit string by making  $O(q_h + Q\ell)$  quantum queries to  $h$ , as follows.

$\mathcal{B}$  is given quantum oracle access to  $h$ , and given a bit string  $X \in \{0, 1\}^{2n}$ , which is  $\rho^h(K)$  ( $K \leftarrow_{\$} \{0, 1\}^k$ ) or chosen uniformly at random. Let  $X_1$  and  $X_2$  be the most significant  $n$ -bit and the least significant  $n$ -bit of  $X$ , respectively. First,  $\mathcal{B}$  runs  $\mathcal{A}$ . When  $\mathcal{A}$  makes a query to the second oracle (which is supposed to be  $h$ ),  $\mathcal{B}$  responds by querying to the oracle of  $h$ . When  $\mathcal{A}$  queries a message  $M$  to the first oracle (which is supposed to be  $\text{HMAC}_K^h$  or  $\widehat{\text{NMAC}}_{K_1, K_2}^h$ ),  $\mathcal{B}$  computes the value  $T := \widehat{\text{NMAC}}_{X_1, X_2}^h(M)$  by making queries to  $h$ , and responds to  $\mathcal{A}$  with  $T$ . Finally  $\mathcal{B}$  returns  $\mathcal{A}$ 's output as its own output.

Then,  $\mathcal{B}$  perfectly simulates  $\text{HMAC}_K^h$  or  $\widehat{\text{NMAC}}_{K_1, K_2}^h$  depending on whether  $X$  is  $\rho^h(K)$  ( $K \leftarrow_{\$} \{0, 1\}^k$ ) or chosen uniformly at random, which implies that  $\mathbf{Adv}_{(\text{HMAC}_K^h, h), (\widehat{\text{NMAC}}_{K_1, K_2}^h, h)}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{\rho^h}^{\text{qPRG}}(\mathcal{B})$ . In addition,  $\mathcal{B}$  makes at most  $O(q_h + Q\ell)$  quantum queries to  $h$ . Thus, from Lemma 2,

$$\mathbf{Adv}_{(\text{HMAC}_K^h, h), (\widehat{\text{NMAC}}_{K_1, K_2}^h, h)}^{\text{dist}}(\mathcal{A}) = \mathbf{Adv}_{\rho^h}^{\text{qPRG}}(\mathcal{B}) \leq O\left(\frac{q_h + Q\ell}{2^{k/2}}\right) \quad (107)$$

follows.

The claim of Lemma 5 follows from (104), (105), and (107).  $\square$

## F Proof of Lemma 6

As mentioned in the proof overview below Lemma 6, in this proof we modify the definition of  $H_i^h$  a little bit. Let  $M = M[1] \| \dots \| M[i]$  be a message of length  $m \cdot i$ . On this input, the value  $H_i^h(M)$  was defined as  $H^h(M) := g_i(M)$  for a random function  $g_i$ , but here we re-define it as

$$H_i^h(M) := f'_{\text{out}}(M, f_i(M)), \quad (108)$$

where  $f'_{out} : \{0, 1\}^{mi} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$  is another random function. Since  $f'_{out}$  is random, this modification does not change the distribution of the function  $H_i^h$ . This section gives a proof only for the case  $i = 1$ . The proof for  $i > 1$  can be done in the same way.

As in Section 2.2, we assume that  $\mathcal{A}$  makes queries to  $H_1^h$  and  $h$  (or,  $H_1^{h'}$  and  $h$ ) in a sequential order. In particular, we assume that  $\mathcal{A}$ 's  $(2i - 1)$ -th query is made to  $H_1^h$  (or  $H_1^{h'}$ ) and  $2i$ -th query is made to  $h$  for  $1 \leq i \leq q$ . (For instance,  $\mathcal{A}$  first queries to  $H_1^h$  (or  $H_1^{h'}$ ) and second queries to  $h$ .) We call queries to  $H_1^h$  and  $H_1^{h'}$  *online queries*, and queries to  $h$  *offline queries* since computations of  $h$  is done offline on adversaries' (quantum) computers in practical settings.

Recall that, when a message  $M$  is queried to an oracle, we implicitly assume that the length of the message  $|M|$  is encoded with  $M$  like  $|(|M|, M)\rangle$  (see the paragraph "Example: Quantum oracle of a fixed function and a quantum random oracle." in Section 2). Since  $H_1^h$  and  $H_1^{h'}$  take messages of different length as inputs, we carefully describe how we implement them. We assume that the unitary operators to process queries to  $H_1^h$  and  $H_1^{h'}$  are implemented as follows.

*Quantum oracle of  $H_1^h$ .*

1. Take  $|M\rangle |y\rangle$  as an input, where  $y \in \{0, 1\}^n$  and  $M \in \{0, 1\}^{mj}$  for some  $1 \leq j \leq \ell$ . For ease of notations, let us define  $M[t] := 0^m$  for  $j + 1 \leq t \leq \ell$ .
2. Query  $M[1]$  to  $f_1$  and obtain

$$|M\rangle |y\rangle \otimes |S_1\rangle, \quad (109)$$

where  $S_1 := f_1(M[1])$ .

3. For  $t = 2, \dots, \ell$ , iteratively compute  $S_t := h(M[t] || S_{t-1})$  by querying  $M[t] || S_{t-1}$  to  $h$ , to obtain

$$|M\rangle |y\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle. \quad (110)$$

4. Copy  $S_j$  into an additional register to obtain

$$|M\rangle |y\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle \otimes |S_j\rangle. \quad (111)$$

5. Query  $S_j$  (in the rightmost register) to  $f_{out}$  and add the result to  $y$  to obtain

$$|M\rangle |y \oplus H_1^h(M)\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle \otimes |S_j\rangle. \quad (112)$$

6. Uncompute Steps 2 - 4 to obtain  $|M\rangle |y \oplus H_1^h(M)\rangle$ .

*Remark 12.* Some readers may wonder why we compute not only  $S_1, \dots, S_j$  but also  $S_{j+1}, \dots, S_\ell$ , and copy  $S_j$  into an auxiliary register. Those operations may seem redundant, but we perform them so that the implementation will be independent of the length of the message. (Among Steps 1-5, only Step 4 depends on the message lengths  $|M|$ .)

Quantum oracle of  $H_1^h$ .

1. Take  $|M\rangle|y\rangle$  as an input, where  $y \in \{0,1\}^n$  and  $M \in \{0,1\}^{mj}$  for some  $1 \leq j \leq \ell$ . For ease of notations, let us define  $M[t] := 0^m$  for  $j+1 \leq t \leq \ell$ .
2. Query  $M[1]$  to  $f_1$  and obtain

$$|M\rangle|y\rangle \otimes |S_1\rangle, \quad (113)$$

where  $S_1 := f_1(M[1])$ .

3. For  $t = 2, \dots, \ell$ , iteratively compute  $S_t := h(M[t]||S_{t-1})$  by querying  $M[t]||S_{t-1}$  to  $h$ , to obtain

$$|M\rangle|y\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle. \quad (114)$$

4. Copy  $S_j$  into an additional register to obtain

$$|M\rangle|y\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle \otimes |S_j\rangle. \quad (115)$$

5. If  $j = 1$ , query  $(M[1], S_1)$  to  $f'_{out}$  and add the result to  $y$  to obtain

$$|M\rangle|y \oplus H_1^h(M)\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle \otimes |S_j\rangle. \quad (116)$$

6. If  $j > 1$ , query  $S_j$  (in the rightmost register) to  $f_{out}$  and add the result to  $y$  to obtain

$$|M\rangle|y \oplus H_1^h(M)\rangle \otimes |S_1\rangle \cdots |S_\ell\rangle \otimes |S_j\rangle. \quad (117)$$

7. Uncompute Steps 2 - 4 to obtain  $|M\rangle|y \oplus H_1^h(M)\rangle$ .

We show the hardness of distinguishing  $H_1^h$  and  $H_1^{h'}$  by using the recording standard oracle with errors (RstOE). We assume that the quantum oracles of  $f_1$ ,  $h$ ,  $f_{out}$ , and  $f'_{out}$  are implemented by using RstOE (quantum queries are processed with RstOE). Let  $\text{RstOE}_{f_1}$ ,  $\text{RstOE}_h$ ,  $\text{RstOE}_{f_{out}}$ , and  $\text{RstOE}_{f'_{out}}$  be the recording standard oracle with errors for  $f_1$ ,  $h$ ,  $f_{out}$ , and  $f'_{out}$ , respectively. We use the symbols  $D_{f_1}$ ,  $D_h$ ,  $D_{f_{out}}$ , and  $D_{f'_{out}}$  to denote databases for  $f_1$ ,  $h$ ,  $f_{out}$ , and  $f'_{out}$ , respectively.

Let  $O_{H_1^h}$  be the unitary operator to process queries to  $H_1^h$  implemented as above. Then,  $O_{H_1^h}$  can be decomposed as

$$O_{H_1^h} = \text{RstOE}_{f_1}^* \cdot \underbrace{\text{RstOE}_h^* \cdots \text{RstOE}_h^*}_{\ell-1 \text{ times}} \cdot \text{CP} \cdot O_{out} \cdot \text{CP} \cdot \underbrace{\text{RstOE}_h \cdots \text{RstOE}_h}_{\ell-1 \text{ times}} \cdot \text{RstOE}_{f_1}, \quad (118)$$

where  $O_{out} = \text{RstOE}_{f_{out}}$  and CP denotes the unitary operator to perform the copy operation in Step 4.

Similarly, let  $O_{H_1^{h'}}$  be the unitary operator to process queries to  $H_1^{h'}$  implemented as above. In addition, let  $\Pi_1$  be the orthogonal projection onto the space spanned by the vectors of messages  $|M\rangle$  such that  $|M| = 1$ . Then,  $O_{H_1^{h'}}$  can be decomposed as

$$O_{H_1^{h'}} = \text{RstOE}_{f_1}^* \cdot \underbrace{\text{RstOE}_h^* \cdots \text{RstOE}_h^*}_{\ell-1 \text{ times}} \cdot \text{CP} \cdot O'_{out} \cdot \text{CP} \cdot \underbrace{\text{RstOE}_h \cdots \text{RstOE}_h}_{\ell-1 \text{ times}} \cdot \text{RstOE}_{f_1}, \quad (119)$$

where  $O'_{out} := \Pi_1 \otimes \text{RstOE}_{f'_{out}} + (I - \Pi_1) \otimes \text{RstOE}_{f_{out}}$ .

**Good and bad databases.** Based on the description above, we introduce the notion of good and bad databases for  $H_1^h$  and  $H_1^{h'}$ .<sup>34</sup>

We say that a (tuple of) valid database  $(D_{f_1}, D_h, D_{f_{out}})$  for  $H_1^h$  is *good* if and only if it satisfies the following properties.

1. For  $(u, \zeta)$  and  $(u', \zeta')$  in  $D_{f_1}$  such that  $u \neq u', \zeta \neq \zeta'$  holds (there is no collision for  $f_1$ ).
2. For  $((v, \zeta), w)$  and  $((v', \zeta'), w')$  in  $D_h$  such that  $(v, \zeta) \neq (v', \zeta'), w \neq w'$  holds (there is no collision for  $h$ ).
3. For all  $(u, \zeta) \in D_{f_1}$  and  $((v, \zeta'), w) \in D_h$ ,  $\zeta \neq w$  holds (there is no collision between outputs of  $f_1$  and  $h$ ).
4. For each  $(\alpha, \beta) \in D_{f_{out}}$ , there exists  $(u, \alpha) \in D_{f_1}$  for some  $u$ , or there exists  $((v, \zeta), \alpha) \in D_h$  for some  $v$  and  $\zeta$ .

We say that  $(D_{f_1}, D_h, D_{f_{out}})$  is *bad* if it is not good.

Similarly, we say that a (tuple of) valid database  $(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})$  for  $H_1^{h'}$  is *good* if and only if it satisfies the following properties.

1. For  $(u, \zeta)$  and  $(u', \zeta')$  in  $D_{f_1}$  such that  $u \neq u', \zeta \neq \zeta'$  holds (there is no collision for  $f_1$ ).
2. For  $((v, \zeta), w)$  and  $((v', \zeta'), w')$  in  $D_h$  such that  $(v, \zeta) \neq (v', \zeta'), w \neq w'$  holds (there is no collision for  $h$ ).
3. For all  $(u, \zeta) \in D_{f_1}$  and  $((v, \zeta'), w) \in D_h$ ,  $\zeta \neq w$  holds (there is no collision between outputs of  $f_1$  and  $h$ ).
4. For each  $(\alpha, \beta) \in D_{f_{out}}$ , there exists  $((v, \zeta), \alpha) \in D_h$  for some  $v$  and  $\zeta$ .
5. For each  $((u, \alpha), \beta) \in D_{f'_{out}}$ ,  $(u, \alpha) \in D_{f_1}$  holds.

We say that  $(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})$  is *bad* if it is not good.

*Intuition behind good and bad databases.* Intuitively, a database  $(D_{f_1}, D_h, D_{f_{out}})$  for  $H_1^h$  is defined to be good if and only if  $D_{f_1}$  does not contain collisions (the first condition on  $H_1^h$ ),  $D_h$  does not contain collisions (the second condition on  $H_1^h$ ), and there is no collision of output values between  $D_{f_1}$  and  $D_h$  (the third condition on  $H_1^h$ ). The fourth condition on  $H_1^h$  is included so that a weird situation such as “ $\alpha$  has been queried to  $f_{out}$ , but both of  $f_1$  and  $h$  have not returned the value  $\alpha$  as output” will not happen for good databases. Good databases for  $H_1^{h'}$  are defined in the same way. Intuitively, a good database changes to bad if and only if an output value of  $f_1$  or  $h$  is randomly sampled at a query, and collide with a previous output of  $f_1$  or  $h$ .

**One-to-one correspondence for good databases.** For a good database  $(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})$  for  $H_1^{h'}$ , let  $\tilde{D}_{f_{out}}$  be the valid database for  $f_{out}$  such that  $(\alpha, \beta) \in \tilde{D}_{f_{out}}$  if and only if  $(\alpha, \beta) \in D_{f_{out}}$  or  $((u, \alpha), \beta) \in D_{f'_{out}}$  for

<sup>34</sup> We use the symbols  $u, \zeta, w, \alpha, \beta, u', \zeta', w', \alpha', \beta'$  to denote  $n$ -bit strings, and use the symbols  $v, v'$  to denote  $m$ -bit strings.

some  $u$ . Then  $(D_{f_1}, D_h, \tilde{D}_{f_{out}})$  becomes a good database for  $H_1^h$ . Let us denote  $(D_{f_1}, D_h, \tilde{D}_{f_{out}})$  by  $[(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})]_{\text{uni}}$  (uni is an abbreviation of “unify”). Then, it is easy to check that the map  $[\cdot]_{\text{uni}} : (D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}}) \mapsto [(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})]_{\text{uni}}$  is a bijection between the set of good databases for  $H_1^h$  and the set of good databases for  $H_1^h$ . Let  $[\cdot]_{\text{sep}}$  (sep is an abbreviation of “separate”) denote the inverse map of  $[\cdot]_{\text{uni}}$ , i.e., the map from the set of good databases for  $H_1^h$  to that for  $H_1^h$  defined by  $[(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})]_{\text{uni}}]_{\text{sep}} = (D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})$ .

The bijections extend to (partially defined) isometries between the state spaces. Let  $\mathcal{H}_{\mathcal{A}}$  be the state space of the adversary, and  $\mathcal{H}_{DB}$  (resp.,  $\mathcal{H}'_{DB}$ ) be the state space of the databases for  $H_1^h$  (resp.,  $H_1^h$ ). In addition, let  $V_{\text{good}} \subset \mathcal{H}_{DB}$  (resp.,  $V'_{\text{good}} \subset \mathcal{H}'_{DB}$ ) be the subspace spanned by good databases. Then, the linear map from  $\mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}$  to  $\mathcal{H}_{\mathcal{A}} \otimes V'_{\text{good}}$  that maps  $|\eta\rangle \otimes |D_{f_1}, D_h, D_{f_{out}}\rangle$  to  $|\eta\rangle \otimes |[D_{f_1}, D_h, D_{f_{out}}]_{\text{sep}}\rangle$  for  $|\eta\rangle \in \mathcal{H}_{\mathcal{A}}$  and a good database  $(D_{f_1}, D_h, D_{f_{out}})$  for  $H_1^h$  becomes an isometry. We denote this isometry and its inverse also by  $[\cdot]_{\text{sep}}$  and  $[\cdot]_{\text{uni}}$ , respectively.

**Notations for state vectors.** Recall that, when an adversary  $\mathcal{A}$  is given oracle accesses to  $H_1^h$  (or  $H_1^h$ ) and  $h$ , we assume that the  $(2i-1)$ -th query is made to  $H_1^h$  (or  $H_1^h$ ) and the  $2i$ -th query is made to  $h$  for  $1 \leq i \leq q$ . Let  $|\phi_{2i-1}\rangle$  be the whole quantum state just before  $\mathcal{A}$ 's  $i$ -th query to  $H_1^h$  when  $\mathcal{A}$  runs relative to  $H_1^h$  and  $h$ . In addition, let  $|\phi_{2i}\rangle$  be the whole quantum state just before  $\mathcal{A}$ 's  $i$ -th query to  $h$  when  $\mathcal{A}$  runs relative to  $H_1^h$  and  $h$ . Define  $|\psi_{2i-1}\rangle$  and  $|\psi_{2i}\rangle$  similarly when  $\mathcal{A}$  runs relative to  $H_1^h$  and  $h$ . For ease of notation, let  $|\phi_{2q+1}\rangle$  and  $|\psi_{2q+1}\rangle$  be the quantum states just before the final measurement when  $\mathcal{A}$  runs relative to  $(H_1^h, h)$  and  $(H_1^h, h)$ , respectively.

We can show that Lemma 6 follows from the proposition below in the same way as we showed Proposition 4 follows from Proposition 5.

**Proposition 9.** *For each  $j = 1, \dots, 2q+1$ , there exist vectors  $|\phi_j^{\text{good}}\rangle$ ,  $|\phi_j^{\text{bad}}\rangle$ ,  $|\psi_j^{\text{good}}\rangle$ , and  $|\psi_j^{\text{bad}}\rangle$  that satisfy the following properties:*

1.  $|\phi_j\rangle = |\phi_j^{\text{good}}\rangle + |\phi_j^{\text{bad}}\rangle$  and  $|\psi_j\rangle = |\psi_j^{\text{good}}\rangle + |\psi_j^{\text{bad}}\rangle$  hold.
2.  $|\phi_j^{\text{good}}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V_{\text{good}}$  and  $|\psi_j^{\text{good}}\rangle \in \mathcal{H}_{\mathcal{A}} \otimes V'_{\text{good}}$ .
3.  $|\phi_{2i-1}^{\text{good}}\rangle = \left[ |\psi_{2i-1}^{\text{good}}\rangle \right]_{\text{uni}}$
4. For a good database  $(D_{f_1}, D_h, D_{f_{out}}, D_{f'_{out}})$  with non-zero coefficient in  $|\psi_{2i-1}^{\text{good}}\rangle$  (resp., in  $|\psi_{2i}^{\text{good}}\rangle$ ),  $|D_{f_1}| \leq 2(i-1)$ ,  $|D_h| \leq (2\ell+1)(i-1)$ ,  $|D_{f_{out}}| \leq i-1$ , and  $|D_{f'_{out}}| \leq i-1$  hold (resp.,  $|D_{f_1}| \leq 2i$ ,  $|D_h| \leq (2\ell+1)(i-1) + 2\ell$ ,  $|D_{f_{out}}| \leq i$ , and  $|D_{f'_{out}}| \leq i$  hold).
5.  $\| |\phi_j^{\text{bad}}\rangle \| \leq \| |\phi_{j-1}^{\text{bad}}\rangle \| + O\left(\ell\sqrt{j\ell/2^n}\right)$  and  $\| |\psi_j^{\text{bad}}\rangle \| \leq \| |\psi_{j-1}^{\text{bad}}\rangle \| + O\left(\ell\sqrt{j\ell/2^n}\right)$  hold (we regard that  $\| |\phi_0^{\text{bad}}\rangle \| = \| |\phi_0^{\text{bad}}\rangle \| = 0$ ).

Intuition behind the claim of this proposition is almost the same for that of Proposition 5 (see explanations below Proposition 5), except that Proposition 9

does not contain a claim on equivalent databases (such as property 4 of Proposition 5).

As we mentioned above, in Proposition 9, a good database changes to bad only when a randomly chosen output of a random function happens to collide with an existing element in databases, like `coll` in Section 1.2. In particular, there does not exist a bad event that corresponds to `hit` in Section 1.2. This is the reason that Proposition 9 does not contain a claim on equivalent databases (recall that equivalent databases are introduced to deal with bad events like `hit`).

Proposition 9 can be shown in a similar way as we showed Proposition 5 by decomposing  $O_{H_1^h}$  and  $O_{H_1'^h}$  as in (118) and (119), respectively, and checking how the quantum states change when  $\text{RstOE}_{f_1}$ ,  $\text{RstOE}_h$ ,  $\text{RstOE}_{f_{out}}$ ,  $\text{RstOE}_{f'_{out}}$ ,  $\text{RstOE}_h^*$ , and  $\text{RstOE}_{f_1}^*$  act in a sequential order. In fact the proof of Proposition 9 is even simpler than the proof of Proposition 5: Proposition 9 can be proven only with the proof techniques used in the previous work [18] because it does not contain claims on equivalent databases.

Hence, in what follows, we omit writing the details and explain only the differences between the proofs of Proposition 9 and Proposition 5. The main differences are summarized as follows.

- D1. Proposition 9 does not contain a claim on equivalent databases (such as property 4 of Proposition 5).
- D2. The oracles  $O_{H_1^h}$  and  $O_{H_1'^h}$  in Proposition 9 take inputs of various lengths while the length of inputs to the oracles in Proposition 5 are fixed.
- D3. The oracles  $O_{H_1^h}$  and  $O_{H_1'^h}$  in Proposition 9 invoke random functions many (about  $2\ell$ ) times whereas the oracles in Proposition 5 do at most only 3 times.

As mentioned before, the difference D1 just simplify some parts of the proof. To translate the proof of Proposition 5 into a proof of Proposition 9, what we have to do about the differences D1 is just to ignore the arguments on property 4 of Proposition 5.

The second difference D2 may look like it make the proof of Proposition 9 complex, but actually it does not. Each message  $M$  is encoded with its length  $|M|$  like  $|(|M|, M)\rangle$ , and the vector  $|(|M|, M)\rangle$  is orthogonal to the vector of another message  $|(|M'|, M')\rangle$  if  $|M'| \neq |M|$ . In addition, the oracles do not affect the message register. Thus, to show the five properties of Proposition 9, it suffices to prove such properties hold when the lengths of all the messages are fixed and equal. When  $|M| \geq 2m$  (i.e.,  $M$  consists of two or more blocks), apparently the behaviors of the oracles  $O_{H_1^h}$  and  $O_{H_1'^h}$  on  $M$  are the same as long as databases are good because  $H_1^h(M) = H_1'^h(M)$ . When  $|M| = m$  (i.e.,  $M$  consists of a single block), we can also prove that the behaviors of  $O_{H_1^h}$  and  $O_{H_1'^h}$  are the same as long as databases are good in a way similar to the proof of Proposition 5. Hence properties 1-4 of Proposition 9 can be shown. The proof for property 5 of Proposition 9 is similar to that for property 6 of Proposition 5, except that the upper bounds of  $\|\phi_j^{\text{bad}}\|$  and  $\|\psi_j^{\text{bad}}\|$  are slightly different. This difference is attributed to D3, which we explain below.

The difference D3 increases the number of total queries made to  $h$  to  $O(\ell q)$ , and the number of elements in the database of  $h$  at the  $i$ -th query to  $O_{H_1^h}$  (resp.,  $O_{H_1'^h}$ ) or at the  $i$ -th offline query to  $h$  becomes  $O(\ell \cdot i)$ . Hence, roughly speaking, the norm of the “bad” vector increases by  $O(\sqrt{\ell i/2^n})$  (but not  $O(\sqrt{i/2^n})$ ) at each query to  $h$  during the  $i$ -th query to  $O_{H_1^h}$  (resp.,  $O_{H_1'^h}$ ) or the  $i$ -th offline query to  $h$ . In addition,  $h$  and  $f_1$  are invoked  $O(\ell)$  times in total at each query to  $O_{H_1^h}$  (resp.,  $O_{H_1'^h}$ ). Hence the upper bound of  $\|\phi_j^{\text{bad}}\|$  in property 5 of Proposition 9 is  $\|\phi_{j-1}^{\text{bad}}\| + O(\ell\sqrt{j\ell/2^n})$  but not  $\|\phi_{j-1}^{\text{bad}}\| + O(\sqrt{j/2^n})$  (resp., the upper bound of  $\|\psi_j^{\text{bad}}\|$  is  $\|\psi_{j-1}^{\text{bad}}\| + O(\ell\sqrt{j\ell/2^n})$  but not  $\|\psi_{j-1}^{\text{bad}}\| + O(\sqrt{j/2^n})$ ), unlike property 6 of Proposition 5.
