Abstract In this paper, we consider the new version of tropical cryptography protocol, i.e the tropical version of ElGamal encryption. We follow the ideas and modify the classical El Gamal encryption using tropical matrices and matrix power in tropical algebra. Then we also provide a toy example for the reader’s understanding.

Keywords STropical algebra · tropical cryptography · El Gamal Encryption.

1 Introduction

El Gamal encryption was invented in 1985 by Taher Gamal [13]. The idea of this algorithm based on the most popular public key exchange protocol, i.e., the Diffie-Hellman protocol. Furthermore, he made the Diffie-Hellman system better and came up with two algorithms that could be used for encryption and authentication. Since ElGamal Encryption using the idea of Diffie-Hellman protocol then the security based on the complexity to solve the discrete logarithm problem (DLP). As we know there is no efficient algorithm can be solved the DLP unless quantum computer can be used.

The effectiveness and safety of any cryptography system are determined by the algorithm and the platform employed. Some researcher are trying to find the best platform to construct the new protocol. There is a new study cryptography in tropical algebra. Tropical algebra studies linear algebra over semiring. Tropical algebra is a semiring \( \mathbb{R} \cup \{ -\infty \} \) endowed with two binary operations i.e maximisation (\( \oplus \)) and addition (\( \otimes \)). The algebraic structure is
denoted by $\mathbb{R}_{\text{max}} = (\mathbb{R} \cup \{-\infty\}, \oplus, \otimes)$. Suppose we have $a, b \in \mathbb{R}_{\text{max}}$, then we define $a \oplus b := \max(a, b)$ and $a \otimes b = a + b$. For further reading in tropical algebra, we can find in, e.g., [8].

Since tropical multiplication is equivalent to addition, computing in a tropical setting is unquestionably faster than its classical analogue. Many previous attempts have been made to provide a practical and safe key exchange mechanism based on tropical matrix algebra. The researchers who introduced the new concept of tropical cryptography are Dima Grigoriev and Vladimir Spilrain [6]. They modify the Stickel’s protocol using polynomial over tropical matrix algebra. Then some studies in tropical cryptography are followed such that [7],[4],[1],[2],[12]. For analysis security the tropical cryptography, there are also some studies such that [10],[3],[5],[11].

Therefore, in this paper we introduce a new tropical version of El Gamal encryption. Using the similar ideas to the classical one we replace the integers number by matrix over tropical algebra. Since the invertible matrices in tropical algebra only diagonal matrix and permutation matrix then we use tropical diagonal matrices for decryption step. We also give a toy example for the reader’s understanding.

2 Tropical Algebra

In this section, we define tropical algebra and tropical matrices in their most fundamental form.

2.1 Basic Definition

Let us introduce the definition of semiring

**Definition 1** Given a non empty set $S$ with two binary operations $+$ and $\times$ then we call $(S, +, \times)$ semiring if for all $a, b, c \in S$ which satisfy the following conditions:

1. $(S, +)$ is an abelian monoid, that means:
   (i) associativity
   \[(a + b) + c = a + (b + c)\].
   (ii) identity element
   \[\exists \in S \text{ such that } \in + a = a + \in = a\].
   (iii) Commutativity
   \[a + b = b + a\].

2. $(S, \times)$ is a monoid, that means
   (i) Associativity
   \[(a \times b) \times c = a \times (b \times c)\].
   (ii) identity element
   \[\exists \in S \text{ such that } \in \times a = a \times \in\].

3. $(S, +, \times)$ is distributive
(i) $a \times (b + c) = a \times b + a \times c$.
(ii) $(b + c) \times a = b \times a + c \times a$.

4. absorbing property of $\mathcal{V}$: $\mathcal{V} \times \mathcal{V} = \mathcal{V} \times \mathcal{V} = \mathcal{V}$

Tropical algebra is one of example of semiring.

Example 1 Let the set $\mathbb{R} \cup \{-\infty\}$ with two binary operations $\oplus$ and $\otimes$ be defined as tropical semiring ($\mathbb{R}_{\text{max}} = (\mathbb{R} \cup \{-\infty\}, \oplus, \otimes)$). For all $a, b \in \mathbb{R}_{\text{max}}$ then we have

$$a \oplus b = \max(a, b), \quad a \otimes b = a + b.$$ 

The element identity respect to maximization and also addition are $-\infty$ and 0, respectively.

2.2 Tropical Matrices

In the section, we will introduce some terms in tropical matrices.

Definition 2 Let us define the tropical matrix identity $I \in \mathbb{R}_{\text{max}}^{n \times n}$ where the diagonal entries equals to 0 and non diagonal entries equals to $-\infty$.

Definition 3 If the diagonal entries of tropical square matrix equal to any numbers in $\mathbb{R}_{\text{max}}$ and non diagonal entries equal to $-\infty$ then we called this kind of matrix as tropical diagonal matrix denoted by $D$.

We can also extend the arithmetic operation of $\oplus$ and $\otimes$ to vectors and matrices as in the following definition:

Definition 4 (Matrix addition and multiplication)

Let $k$ be a scalar in $\mathbb{R}_{\text{max}}$ and matrix $A = (a_{ij}) \in \mathbb{R}_{\text{max}}^{m \times n}$, (i.e tropical matrix with dimension $m \times n$), then we define

$$(k \otimes A)_{ij} = k \otimes (a_{ij}), \forall i = 1, \ldots, m \text{ and } j = 1, \ldots, n.$$ 

If we have two tropical matrices $A = (a_{ij})$ and $B = (b_{ij})$ with the same dimension $m \times n$, then we define

$$(A \oplus B)_{ij} = \max(a_{ij}, b_{ij}), \forall i = 1, \ldots, m \text{ and } j = 1, \ldots, n.$$ 

If we have two matrices $A = (a_{ij}) \in \mathbb{R}_{\text{max}}^{m \times p}$ and $B = (b_{ij}) \in \mathbb{R}_{\text{max}}^{p \times n}$ then we define

$$(A \otimes B)_{ij} = \bigoplus_{k=1}^{p} a_{ik} \otimes b_{kj}, \forall i = 1, \ldots, m \text{ and } j = 1, \ldots, n.$$ 

Next, we will discuss the definition of tropical matrix powers.
Definition 5 (Tropical matrix powers)
Let $A$ be a tropical square matrix. Then we define the $n$th tropical matrix power of $A$ as

$$A^\otimes n = A \otimes A \otimes \ldots \otimes A.$$ 

We have $A^\otimes 0 = I$.

We can also study the behaviour of tropical matrix powers [9] and apply it for analyse the security of our cryptosystem.

3 Tropical Version of El Gamal Encryption

We first recall the classical version of ElGamal encryption as follows:

**Algorithm 1** (ElGamal Encryption).

*Alice and Bob agree on public parameter: finite group $\mathbb{Z}_p$, prime number $p$ and generator $g \in \mathbb{Z}_p$.

**Key Generation**

In this part, Alice will generate her public key and sends it to Bob.

1. Alice chooses random integer number $x$ and computes $u = g^x \mod p$.
2. Alice sends the public key $u$ to Bob.

**Encryption**

Bob is here with a message $m$ and he wants to send the message to Alice. In order to protect his message then Bob encrypt the message as follows

- Bob randomly chooses integer number $y$.
- Bob computes his public key $v = g^y$.
- Bob then computes his secret key using $u$ and get $K_B = (u)^y \mod p$
- Using his secret key $K_B$ then he decrypt the message into cipher text $c = m \otimes S$.
- Bob then sends $c$ and $v$ to Alice.

**Decryption**

In order to reveal the message $m$, Alice does the following step:

- Compute $K_A = v^x$.
- Compute $m = c \otimes K^\otimes -1_A$.

Following the idea of classical ElGamal encryption then we modify the algorithm (1) using matrix over tropical algebra.

Let us define the set $\mathbb{Z} \cup \{\infty\}$ subset of $\mathbb{R} \cup \{-\infty\}$ then we can also define the subsemiring $\mathbb{Z}_{\text{max}}$ of $\mathbb{R}_{\text{max}}$. in this paper we use $\mathbb{Z}_{\text{max}}$ instead of $\mathbb{R}_{\text{max}}$.

We next introduce the tropical version of ElGamal Encryption.

**Algorithm 2** (Tropical ElGamal Encryption).

*Alice and Bob agree on public parameters: prime number $p$ and matrix $G \in M_n(\mathbb{Z}_{\text{max}})$ (i.e matrix $n \times n$ with entries in $\mathbb{Z}_{\text{max}}$).
1. **Key Generation**
   - Alice chooses a random integer $x$.
   - Alice computes $U = G^x \mod p$ and sends it to Bob.

2. **Encryption**
   Bob has message $m$.
   - Bob randomly chooses integer number $y$.
   - Bob computes $K_B = U^y \mod p$.
   - He computes $V = G^y$.
   - Bob change matrix $K_B$ to matrix diagonal form and then encrypts the message $c = m \otimes K_B$.
   - Then Bob sends $c$ and $V$ to Alice.

3. **Decryption**
   Alice then decrypts the message in the following steps:
   - Alice computes her private key $K_A = V^x$ and then change it to diagonal matrix.
   - Alice decrypts the message $m = m \otimes K_A^{-1}$

Since the invertible matrices in tropical algebra only tropical diagonal matrices dan permutation matrices then we transform the secret key of Alice $K_A$ and the secret key of Bob $K_B$ to diagonal matrices (replace non diagonal entries with $-\infty$).

4. **A Toy Example**

We give a toy example as follows: Let Alice and Bob agree on public parameter $p = 73$ and public matrix $G = \begin{pmatrix} 67 & 71 \\ 23 & 56 \end{pmatrix} \in M_2(\mathbb{Z}_{\text{max}})$.

**Key Generation**
In this part, Alice generates the public key and private key in the following steps:

1. Alice picks at random integer number $x = 57$.
2. Alice computes her public key $U = G^x = \begin{pmatrix} 67 & 71 \\ 23 & 56 \end{pmatrix}^{57} = \begin{pmatrix} 819 & 3823 \\ 3775 & 3779 \end{pmatrix} \mod 73 = \begin{pmatrix} 23 & 27 \\ 52 & 56 \end{pmatrix}$.
3. Alice sends $U$ to Bob.

**Encryption**
In this part, Bob has a message $M = \text{Eve want to kill you}$. Before he sends the message to Alice then Bob divide the message into some blocks of matrices as follows:

$$
\begin{align*}
    m_1 &= \begin{pmatrix} E & v \\ e & \text{space} \end{pmatrix},
    m_2 &= \begin{pmatrix} w & a \\ n & t \end{pmatrix},
    m_3 &= \begin{pmatrix} t & 0 \\ \text{space} & k \end{pmatrix},
    m_4 &= \begin{pmatrix} i & l \\ 1 & u \end{pmatrix},
    m_5 &= \begin{pmatrix} y & 0 \\ u & \text{space} \end{pmatrix}
\end{align*}
$$

Then Bob needs to encrypt the message in the following steps:
1. Bob translates the message into ASCII code as follows:

\[
\begin{align*}
    m_1 &= \begin{pmatrix} 69 & 118 \\ 101 & 32 \end{pmatrix},
m_2 &= \begin{pmatrix} 119 & 97 \\ 110 & 16 \end{pmatrix},
m_3 &= \begin{pmatrix} 116 & 111 \\ 32 & 107 \end{pmatrix},
m_4 &= \begin{pmatrix} 105 & 108 \\ 108 & 32 \end{pmatrix},
m_5 &= \begin{pmatrix} 121 & 111 \\ 117 & 32 \end{pmatrix}.
\end{align*}
\]

2. Bob picks integer \( y = 43 \).

3. He computes \( K_B = U \otimes y = (G \otimes x)^y \mod 73 = \begin{pmatrix} 39 \\ 68 \\ 43 \\ 72 \end{pmatrix} \).

4. Bob also computes his public key \( V = G \otimes y = \begin{pmatrix} 2881 \\ 2885 \\ 2837 \\ 2841 \end{pmatrix} \mod 73 = \begin{pmatrix} 0 \\ 4 \\ 42 \\ 3 \end{pmatrix} \).

5. Bob changes matrix \( K_B \) into diagonal matrix and we have \( K_B = \begin{pmatrix} 39 & -\infty \\ -\infty & 72 \end{pmatrix} \).

6. Bob computes \( c_i = m_i \otimes S \) for \( i = 1, \ldots, 5 \) and we have the following cipher text:

\[
\begin{align*}
    c_1 &= \begin{pmatrix} 108 & 190 \\ 140 & 104 \end{pmatrix},
c_2 &= \begin{pmatrix} 158 & 169 \\ 149 & 88 \end{pmatrix},
c_3 &= \begin{pmatrix} 155 & 183 \\ 71 & 179 \end{pmatrix},
c_4 &= \begin{pmatrix} 144 & 180 \\ 147 & 104 \end{pmatrix},
c_5 &= \begin{pmatrix} 160 & 183 \\ 156 & 104 \end{pmatrix}.
\end{align*}
\]

7. Bob sends \( c_i \) and \( V \) to Alice.

**Decryption**

After Alice receives the cipher text \( c_i \) and public key \( V \). Then she decrypts the cipher text to reveal the message.

1. Alice then computes \( K_A = V \otimes x = (G \otimes x)^{-x} \), and Alice transform \( S \) into diagonal matrix \( S = \begin{pmatrix} 39 & -\infty \\ -\infty & 72 \end{pmatrix} \).

2. Alice decrypts the cipher text \( d = c_i \otimes K_A^{-1} \) and then reveal the message from Bob: Eve want to kill you.

5 Conclusions

In this paper, a new version of ElGamal encryption based on tropical matrices are presented. This new version using tropical matrix powers and diagonal matrices. We also give a toy example. We give a suggestion for parameters to avoid brute attack. For further research, we will consider to analyse the security using tropical discrete logarithm problem [3].
