#### Abstract

In this work, we propose the first identity-based matchmaking encryption (IB-ME) scheme under the standard assumptions in the standard model. This scheme is proven to be secure under the symmetric external Diffie-Hellman (SXDH) assumption in prime order bilinear pairing groups. In our IB-ME scheme, all parameters have constant number of group elements and are simpler than those of previous constructions. Previous works are either in the random oracle model or based on the q-type assumptions, while ours is built directly in the standard model and based on static assumptions, and does not rely on other crypto tools.

More concretely, our IB-ME is constructed from a variant of twolevel anonymous IBE. We observed that this two-level IBE with anonymity and unforgeability satisfies the same functionality of IB-ME, and its security properties cleverly meet the two requirements of IB-ME (Privacy and Authenticity). The privacy property of IB-ME relies on the anonymity of this two-level IBE, while the authenticity property is corresponding to the unforgeability in the 2nd level. This variant of two-level IBE is built from dual pairing vector spaces, and both security reductions rely on dual system encryption.

Keywords: Matchmaking encryption • Identity-based encryption • Standard assumptions • Standard model

## 1 Introduction

Matchmaking Encryption (ME) is a new form of encryption proposed by Ateniese et al. [3] in Crypto 2019, in which both the sender and the receiver (each with its own attributes) can specify fine-grained access policies the other party must satisfy in order for the message to be revealed. Using ME, a sender with attributes $\sigma \in\{0,1\}^{*}$ encrypts messages after generating the policy $\mathbb{R}$ of the intended receiver, and a receiver with attributes $\rho \in\{0,1\}^{*}$ obtains a decryption key $d k_{\mathbb{S}}$ from an authority before decrypting the ciphertext from a sender
satisfying the specified policy $\mathbb{S}$. This receiver will correctly decrypt the ciphertext and obtain the message if and only if the sender's attributes $\sigma$ match the policy $\mathbb{S}$ specified by the receiver, and at the same time the receiver's attributes $\rho$ match the policy $\mathbb{R}$ specified by the sender. The implementation of matchmaking encryption in an identity-based setting is dubbed identity-based matchmaking encryption (IB-ME), where both the sender and the receiver specify a single identity instead of general policies.

Differently from ME, each identity is chosen by the sender or receiver on the fly without talking to the authority in an identity-based setting. Now each identity $x \in\{0,1\}^{*}$ will represent an access policy $\mathbb{A}$, which means that we use snd and rcv to represent the target policies $\mathbb{S}$ and $\mathbb{R}$ specified by the receiver and the sender, respectively. The sender's identity $\sigma \in\{0,1\}^{*}$ and its target policies rcv can be embedded in the ciphertext. The receiver with an identity $\rho$ can now additionally specify a target identity snd $\in\{0,1\}^{*}$ on the fly, and obtain the correct message as long as the sender's identity $\sigma$ match the receiver's policy snd and vice-versa (i.e., $\rho=\mathrm{rcv}$ and $\sigma=$ snd). From this perspective, IB-ME can be considered as a more expressive version and generalization of anonymous identity-based encryption, in which both the sender and the receiver can specify a target communicating entity in a privacy-preserving manner.

Ateniese et al. [3] provide generic frameworks for constructing ME from functional encryption and propose the first IB-ME scheme with provable security under the bilinear Diffie-Hellman (BDH) assumption, but in the random oracle model. They also deploy experiments to prove their construction is practical and created an anonymous bulletin board over a Tor network. Following their work, Francati et al. [15] give the first IB-ME construction satisfying privacy in the plain model (without random oracles), but based on q-ABDHE assumption and non-interactive zero-knowledge (NIZK) proof systems. Meanwhile, they exhibit a generic transform taking as input any private IB-ME and outputting an IBME satisfying both enhanced privacy and authenticity. These leave the following problem:

## Can we construct IB-ME under the standard assumptions in the standard model?

### 1.1 Our Results

In this work, we present the first IB-ME scheme under the standard assumptions in the standard model. This scheme is based on the SXDH assumption in prime order bilinear pairing groups. The construction is direct and does not rely on other cryptographic tools such as non-interactive zero-knowledge proof systems. We summarize existing IB-ME schemes in Table 1 and several salient features of this work from the following two aspects:

- First, we adopt a variant of two-level IBE with anonymity modified from Chen's anonymous IBE and signature scheme [12] to form our construction. This two-level IBE with anonymity and unforgeability satisfies the same

| Reference | Model | Assumption |
| :---: | :---: | :---: |
| AFNV19 [3] | Random Oracle | BDH |
| FGRV21 [15] | Standard | q-ABDHE+NIZK |
| Ours | Standard | SXDH |

Table 1. Comparison with existing IB-ME schemes
functionality of IB-ME, and its security properties cleverly meet the two requirements of IB-ME (privacy and authenticity). The privacy property of IB-ME relies on the anonymity of the 1st level IBE, while the authenticity property is corresponding to the unforgeability in the 2nd level. The usage of this variant of two-level anonymous IBE allows our scheme to technically ensure that the identities chosen by the sender and receiver can be checked simultaneously without revealing any information other than whether the match is successful or not.

- Second, this variant of two-level IBE is built from Okamoto and Takashima's dual pairing vector spaces [24] and its security reductions rely on Waters's dual system encryption [31]. During the security proof process, we draw on the idea of delegation functionality in Okamoto and Takashima's hierarchical inner-product encryption [25] and slightly extended the dual system methodology to fit our IB-ME scheme. We rely on an information theoretic argument instead of computational arguments in the final step of the proof. This is the first work to build identity-based matchmaking encryption by combining dual pairing vector spaces and dual system encryption under the standard assumptions.

### 1.2 Technical Overview

To achieve the above results, we propose a new technique for designing IB-ME schemes, its construction is straightforward and does not rely on other crypto tools. More concretely, we present a variant of two-level IBE with anonymity and unforgeability that satisfies the same functionality of IB-ME. Moreover, its security properties cleverly meet the two requirements of IB-ME (privacy and authenticity). An IB-ME scheme consists of five algorithms, namely Setup that generates the master public key $m p k$ and master secret key $m s k$, SKGen that generates the encryption key $e k_{\sigma}$ using the sender's identity $\sigma$, RKGen that generates the decryption key $d k_{\rho}$ using the receiver's identity $\rho$, Enc that encrypts the message using $e k_{\sigma}$ and a target identity rcv, and Dec that decrypts the ciphertext using $d k_{\rho}$ and a target identity snd. Decryption can be successful if and only if the attributes of the sender and receiver satisfy the target identity respectively, i.e. $\sigma=$ snd $\wedge \rho=\mathrm{rcv}$. At the same time, an IB-ME should satisfy two main security properties: privacy and authenticity [3].

Informally, in this variant of two-level IBE, the algorithms RKGen and Enc associated by identities $\rho$ and rcv are the first level, while the second level consists of the algorithms SKGen and Dec associated by identities $\sigma$ and snd. The

Fig. 1. Security requirements of IB-ME
privacy property of IB-ME relies on the anonymity of this 2-level IBE, while the authenticity property is corresponding to the unforgeability in the 2nd level as all shown in Fig. 1. Decryption can only be done when both levels are matched successfully. Different from IBE, a part of the two keys $e k_{\sigma}, d k_{\rho}$ need to be generated from $m s k$, and each identity-related parameter needs to be generated separately. More concretely, it can be observed that in game $\mathbf{G}_{\Pi, \mathrm{A}}^{\mathrm{ib-priv}}(\lambda)$ defining privacy, the adversary outputs two sets of challenge pairs ( $m_{0}, \mathrm{rcv}_{0}, \sigma_{0}$ ) and ( $m_{1}, \mathrm{rcv}_{1}, \sigma_{1}$ ) after querying oracles, and then outputs $b^{\prime}$ for guessing. In game $\mathrm{G}_{\Pi, \mathrm{A}}^{\mathrm{ib}-\text { auth }}(\lambda)$ defining authenticity, the adversary is actually similar to being unable to forge a ciphertext $c t$ about the message $m$. The former can be considered as a property of anonymity, while the latter generates an unforgeable signature. Therefore, a two-level anonymous IBE (a signature scheme can be derived from the same IBE) can be used to instantiate this construction and can achieve the security requirements simultaneously.

Our first thought was to use Lewko-Waters composite order IBE scheme [20] for the advantage of its efficiency and shorter parameters, but in view of its difficulty in extending to high-dimensional spaces, we finally decided to choose the prime-order group IBE scheme based on DPVS as the basis of our construction. Meanwhile, since a part of the decryption key $d k_{\rho}$ needs to be generated from $m s k$, we borrow some ideas from constructing hierarchical inner-product predicate encryption. Specifically, Chen's anonymous IBE [12] and Okamoto and Takashima's HIPE [25] together form the blueprint of this variant of two-level IBE. Thus the message and all identities can be hidden in the high-dimensional basis vectors of the linear subspace. As for security, the privacy property is consistent with proving the full security and anonymity of the 1st level IBE through the dual system encryption methodology. When proving the authenticity property which is similar to the unforgeability of signatures, we make a transformation
from IB-ME to IBE and land it on the security of this IBE system. The rest of the proof is similar to that in $[12,18]$.

### 1.3 Related Work

The idea of using some unique information about the identity of a user as his public encryption key was conceived by Shamir [29] in 1984 and is known as Identity-Based Encryption (IBE). In an identity-based encryption system, a sender who has access to the public parameters can encrypt a message using the target receiver's identity, and the ciphertext can only be decrypted by a receiver who satisfies this identity. We now have constructions of IBE schemes from a large class of assumptions, namely pairings, quadratic residuosity and lattices, starting with the early constructions in the random oracle model $[7,14,16]$, to more recent constructions in the standard model [5,6,9,2,13].

In order to overcome the limitations of partitioning [30], Waters presented a new methodology dubbed dual system encryption [31] for obtaining fully secure IBE and HIBE systems from simple assumptions. It was further developed in several subsequent works $[20,21,22,23]$ by Lewko and Waters to enhance the security and the efficiency. Most of these works have used composite order groups as a convenient setting for instantiating the dual system, but with the introduction of dual pairing vector spaces (DPVS) by Okamoto and Takashima [24,25,27], which is a brand new technique based on bilinear pairing groups of prime order, some practical and flexible works emerged. A number of functional encryption schemes [19,26,28,12] that intelligently combine dual system encryption and DPVS have a better performance. Then Lewko et al. successfully explored a general framework [18] based on pair encoding [4] summarized by Attrapadung for converting composite order pairing-based cryptosystems into prime order settings and obtained fully secure IBE and HIBE schemes. Chen et al. presented a modular framework [10] based on predicate encodings [32] proposed by Wee for the design of efficient adaptively secure attribute-based encryption (ABE) schemes for a large class of predicates under the standard k -Lin assumption in prime-order groups and obtained concrete efficiency improvements for several ABE schemes.

The notion of IB-ME proposed by Ateniese et al. in [3] is a generalization of IBE where the sender and the receiver can both specify a target identity. Following their works, Xu et al. [33] proposed matchmaking attribute-based encryption by extending the IB-ME scheme, and apply it to construct a secure fine-grained bilateral access control data sharing system in cloud-fog computing. They also introduced a new cryptographic tool called lightweight matchmaking encryption [34] and constructed a secure cloud-fog IoT data sharing system with bilateral access control.

Organization : The rest of this paper is organized as follows: Section 2 introduces the necessary preliminaries on dual pairing vector spaces and SXDH assumption. We give the definitions of IBE and recall the syntax and security of IB-ME in Section 3. We detail our scheme and prove its security in Section 4. A brief conclusion and future works are in Section 5.

## 2 Preliminaries

In what follows, we first introduce some notations used in this work. Then we give a few preliminaries related to groups with efficiently computable bilinear maps and define the Symmetric External Diffie-Hellman assumption.

Notation: If S is a finite set, then $r \stackrel{R}{\leftarrow}$ S denotes sampling $r$ uniformly at random from S . If $f$ is an algorithm or function, then $y \leftarrow f(x)$ denotes the output of this algorithm with $x$ as input. $y:=x$ denotes that $y$ is defined or substituted by $x$. Unless otherwise specified, algorithms in this work are randomized and PPT stands for probabilistic polynomial time. We use lowercase letters (e.g., $r, s, t$ ) to denote elements in vectors or matrices, bold lowercase letters (e.g., $\mathbf{b}_{\mathbf{1}}, \mathbf{d}_{\mathbf{2}}, \mathbf{f}_{\mathbf{3}}^{*}$ ) to denote vectors and bold uppercase letters (e.g., A) to denote matrices. We say a function $\varepsilon(\lambda)$ is negligible in $\lambda$, if $\varepsilon(\lambda)=o\left(1 / \lambda^{c}\right)$ for every $c \in \mathbb{Z}$, and we write $\operatorname{neg}(\lambda)$ to denote a negligible function in $\lambda$.

### 2.1 Dual Pairing Vector Spaces

Our constructions are based on dual pairing vector spaces proposed by Okamoto and Takashima [24,25]. In this work, we concentrate on the asymmetric version [26]. We only briefly describe how to generate random dual orthonormal bases. See $[24,25,26]$ for a full definition of dual pairing vector spaces.

Definition 1 (Asymmetric bilinear pairing groups). Asymmetric bilinear pairing groups $\left(q, G_{1}, G_{2}, G_{T}, g_{1}, g_{2}, e\right)$ are a tuple of a prime $q$, cyclic (multiplicative) groups $G_{1}, G_{2}$ and $G_{T}$ of order $q, g_{1} \neq 1 \in G_{1}, g_{2} \neq 1 \in G_{2}$, and a polynomial-time computable nondegenerate bilinear pairing $e: G_{1} \times G_{2} \rightarrow G_{T}$ i.e., $e\left(g_{1}^{s}, g_{2}^{t}\right)=e\left(g_{1}, g_{2}\right)^{s t}$ and $e\left(g_{1}, g_{2}\right) \neq 1$.

In addition to referring to individual elements of $G_{1}$ and $G_{2}$, we will also consider "vectors" of group elements. For $\mathbf{v}=\left(v_{1}, \ldots, v_{n}\right) \in \mathbb{Z}_{q}^{n}$ and $g_{\beta} \in G_{\beta}$, we write $g_{\beta}^{\mathbf{v}}$ to denote an $n$-tuple of elements of $G_{\beta}$ for $\beta=1,2$ :

$$
g_{\beta}^{\mathbf{v}}:=\left(g_{\beta}^{v_{1}}, \ldots, g_{\beta}^{v_{n}}\right)
$$

For any $a \in \mathbb{Z}_{q}$ and $\mathbf{v}, \mathbf{w} \in \mathbb{Z}_{q}^{n}$, we have :

$$
g_{\beta}^{a \mathbf{v}}:=\left(g_{\beta}^{a v_{1}}, \ldots, g_{\beta}^{a v_{n}}\right), \quad g_{\beta}^{\mathbf{v}+\mathbf{w}}:=\left(g_{\beta}^{v_{1}+w_{1}}, \ldots, g_{\beta}^{v_{n}+w_{n}}\right)
$$

Then we define

$$
e\left(g_{1}^{\mathbf{v}}, g_{2}^{\mathbf{w}}\right):=\prod_{i=1}^{n} e\left(g_{1}^{v_{i}}, g_{2}^{w_{i}}\right)=e\left(g_{1}, g_{2}\right)^{\mathbf{v} \cdot \mathbf{w}}
$$

Here, the dot product is taken modulo $q$.

Dual Pairing Vector Spaces. For a fixed (constant) dimension $n$, we will choose two random bases $\mathbb{B}:=\left(\mathbf{b}_{1}, \ldots, \mathbf{b}_{n}\right)$ and $\mathbb{B}^{*}:=\left(\mathbf{b}_{1}^{*}, \ldots, \mathbf{b}_{n}^{*}\right)$ of $\mathbb{Z}_{q}^{n}$, subject to the constraint that they are "dual orthonormal", meaning that

$$
\mathbf{b}_{j} \cdot \mathbf{b}_{k}^{*}=0(\bmod q)
$$

whenever $j \neq k$, and

$$
\mathbf{b}_{j} \cdot \mathbf{b}_{j}^{*}=\psi(\bmod q)
$$

for all $j$, where $\psi$ is a random element of $\mathbb{Z}_{q}$. We denote such algorithm as Dual $\left(\mathbb{Z}_{q}^{n}\right)$.

Then for generators $g_{1} \in G_{1}$ and $g_{2} \in G_{2}$, we have

$$
e\left(g_{1}^{\mathbf{b}_{j}}, g_{2}^{\mathbf{b}_{k}^{*}}\right)=1
$$

whenever $j \neq k$, where 1 here denotes the identity element in $G_{T}$.
More generally, we can sample multiple tuple of "dual orthonormal" bases. Namely, for fixed (constant) dimension $n_{1}, \ldots, n_{d}$, we will choose $d$ tuples of two random bases $\mathbb{B}_{i}:=\left(\mathbf{b}_{1, i}, \ldots, \mathbf{b}_{n_{i}, i}\right)$ and $\mathbb{B}_{i}^{*}:=\left(\mathbf{b}_{1, i}^{*}, \ldots, \mathbf{b}_{n_{i}, i}^{*}\right)$ of $\mathbb{Z}_{q}^{n_{i}}$, subject to the constraint that they are "dual orthonormal", meaning that

$$
\mathbf{b}_{j, i} \cdot \mathbf{b}_{k, i}^{*}=0(\bmod q)
$$

whenever $j \neq k$, and

$$
\mathbf{b}_{j, i} \cdot \mathbf{b}_{j, i}^{*}=\psi(\bmod q)
$$

for all $j$, where $\psi$ is a random element of $\mathbb{Z}_{q}$. We denote such algorithm as Dual $\left(\mathbb{Z}_{q}^{n_{1}}, \ldots, \mathbb{Z}_{q}^{n_{d}}\right)$.

### 2.2 SXDH Assumptions

Definition 2 (DDH1: Decisional Diffie-Hellman Assumption in $G_{1}$ ). Given a group generator $\mathcal{G}$, we define the following distribution:

$$
\begin{aligned}
& \mathbb{G}:=\left(q, G_{1}, G_{2}, G_{T}, g_{1}, g_{2}, e\right) \stackrel{R}{\leftarrow} \mathcal{G}, \\
& a, b, c \stackrel{R}{\leftarrow} \mathbb{Z}_{q}, \\
& D:=\left(\mathbb{G} ; g_{1}, g_{2}, g_{1}^{a}, g_{1}^{b}\right) .
\end{aligned}
$$

We assume that for any PPT algorithm $\mathcal{A}$ (with output in $\{0,1\}$ ),

$$
\operatorname{Adv}_{\mathcal{A}}^{\mathrm{DDH} 1}(\lambda):=\left|\operatorname{Pr}\left[\mathcal{A}\left(D, g_{1}^{a b}\right)\right]-\operatorname{Pr}\left[\mathcal{A}\left(D, g_{1}^{a b+c}\right)\right]\right|
$$

is negligible in the security parameter $\lambda$.
The dual of above assumption is Decisional Diffie-Hellman assumption in $G_{2}$ (denoted as DDH2), which is identical to Definition 2 with the roles of $G_{1}$ and $G_{2}$ reversed. We say that:

Definition 3. The Symmetric External Diffie-Hellman assumption holds if DDH problems are intractable in both $G_{1}$ and $G_{2}$.

### 2.3 Subspace Assumptions via SXDH

In this subsection, we present subspace assumptions derived from the SXDH assumption. We will rely on these assumptions later to instantiate our encryption schemes. These are analogues of the DLIN-based Subspace assumptions given in [11,18,26].

Definition 4 (DS1: Decisional Subspace Assumption in $G_{1}$ ). Given a group generator $\mathcal{G}(\cdot)$, define the following distribution:

$$
\begin{aligned}
& \mathbb{G}:=\left(q, G_{1}, G_{2}, G_{T}, g_{1}, g_{2}, e\right) \stackrel{R}{\leftarrow} \mathcal{G}\left(1^{\lambda}\right), \\
& \left(\mathbb{B}, \mathbb{B}^{*}\right) \stackrel{R}{\leftarrow} \operatorname{Dual}\left(\mathbb{Z}_{q}^{N}\right) ; \tau_{1}, \tau_{2}, \mu_{1}, \mu_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}, \\
& U_{1}:=g_{2}^{\mu_{1} \mathbf{b}_{1}^{*}+\mu_{2} \mathbf{b}_{K+1}^{*}}, \ldots, U_{K}:=g_{2}^{\mu_{1} \mathbf{b}_{K}^{*}+\mu_{2} \mathbf{b}_{2 K}^{*}}, \\
& V_{1}:=g_{1}^{\tau_{1} \mathbf{b}_{1}}, \ldots, V_{K}:=g_{1}^{\tau_{1} \mathbf{b}_{K}}, \\
& W_{1}:=g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{K+1}}, \ldots, W_{K}:=g_{1}^{\tau_{1} \mathbf{b}_{K}+\tau_{2} \mathbf{b}_{2 K}}, \\
D:= & \left(\mathbb{G} ; g_{2}^{\mathbf{b}_{1}^{*}}, \ldots, g_{2}^{\mathbf{b}_{K}^{*}}, g_{2}^{\mathbf{b}_{2 K+1}^{*}}, \ldots, g_{2}^{\mathbf{b}_{N}^{*}}, g_{1}^{\mathbf{b}_{1}}, \ldots, g_{1}^{\mathbf{b}_{N}}, U_{1}, \ldots, U_{K}, \mu_{2}\right)
\end{aligned}
$$

where $K, N$ are fixed positive integers that satisfy $2 K \leq N$. We assume that for any PPT algorithm $\mathcal{A}$ (with output in $\{0,1\}$ ),

$$
\operatorname{Adv}_{\mathcal{A}}^{\mathrm{DS} 1}(\lambda):=\left|\operatorname{Pr}\left[\mathcal{A}\left(D, V_{1}, \ldots, V_{K}\right)=1\right]-\operatorname{Pr}\left[\mathcal{A}\left(D, W_{1}, \ldots, W_{K}\right)=1\right]\right|
$$

is negligible in the security parameter $\lambda$.
For our construction, we only require the assumption for $K=4$ and $N=8$. Furthermore, we do not need to provide $\mu_{2}$ to the distinguisher. Informally, this means that, given $\tau_{1}, \tau_{2}, \mu_{1}, \mu_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and

$$
U_{1}=g_{2}^{\mu_{1} \mathbf{b}_{1}^{*}+\mu_{2} \mathbf{b}_{5}^{*}}, U_{2}=g_{2}^{\mu_{1} \mathbf{b}_{2}^{*}+\mu_{2} \mathbf{b}_{\mathbf{6}}^{*}}, U_{3}=g_{2}^{\mu_{1} \mathbf{b}_{3}^{*}+\mu_{2} \mathbf{b}_{7}^{*}}, U_{4}=g_{2}^{\mu_{1} \mathbf{b}_{4}^{*}+\mu_{2} \mathbf{b}_{\mathbf{8}}^{*}},
$$

the distributions $\left(V_{1}, V_{2}, V_{3}, V_{4}\right)$ and $\left(W_{1}, W_{2}, W_{3}, W_{4}\right)$ are computationally indistinguishable, where:

$$
\begin{aligned}
& V_{1}=g_{1}^{\tau_{1} \mathbf{b}_{1}}, V_{2}=g_{1}^{\tau_{1} \mathbf{b}_{2}}, V_{3}=g_{1}^{\tau_{1} \mathbf{b}_{3}}, V_{4}=g_{1}^{\tau_{1} \mathbf{b}_{4}} ; \\
& W_{1}=g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{5}}, W_{2}=g_{1}^{\tau_{1} \mathbf{b}_{2}+\tau_{2} \mathbf{b}_{6}}, W_{3}=g_{1}^{\tau_{1} \mathbf{b}_{3}+\tau_{2} \mathbf{b}_{7}}, W_{4}=g_{1}^{\tau_{1} \mathbf{b}_{4}+\tau_{2} \mathbf{b}_{8}} .
\end{aligned}
$$

Lemma 1. If the $D D H$ assumption in $G_{1}$ holds, then the Subspace assumption in $G_{1}$ stated in Definition 4 also holds. More precisely, for any adversary $\mathcal{A}$ against the Subspace assumption in $G_{1}$, there exist probabilistic algorithms $\mathcal{B}$ whose running times are essentially the same as that of $\mathcal{A}$, such that

$$
\operatorname{Adv}_{\mathcal{A}}^{\mathrm{DS} 1}(\lambda) \leq \operatorname{Adv}_{\mathcal{B}}^{\mathrm{DDH} 1}(\lambda)
$$

Proof. Detailed proofs can be found in [11].
The dual of the Subspace assumption in $G_{1}$ is Subspace assumption in $G_{2}$ (denoted as DS2), which is identical to Definition 4 with the roles of $G_{1}$ and $G_{2}$ reversed. Similarly, we can prove that the Subspace assumption holds in $G_{2}$ if the DDH assumption in $G_{2}$ holds.

### 2.4 Statistical Indistinguishability Lemma

We require the following lemma for our security proofs, which is derived from [26].

Lemma 2. For $p \in \mathbb{Z}_{q}$, let $C_{p}:=\left\{(\mathbf{x}, \mathbf{v}) \mid \mathbf{x} \cdot \mathbf{v}=p, \mathbf{0} \neq \mathbf{x}, \mathbf{0} \neq \mathbf{v} \in \mathbb{Z}_{q}^{n}\right\}$. For all $(\mathbf{x}, \mathbf{v}) \in C_{p}$, for all $(\mathbf{z}, \mathbf{w}) \in C_{p}$, and $\mathbf{A} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}^{n \times n}$ ( $\mathbf{A}$ is invertible with overwhelming probability),

$$
\operatorname{Pr}\left[\mathbf{x} \mathbf{A}^{\top}=\mathbf{z} \wedge \mathbf{v A}^{-1}=\mathbf{w}\right]=\frac{1}{\# C_{p}}
$$

## 3 Identity-Based Matchmaking Encryption

In what follows, we first recall the definitions of identity-based encryption and signatures. Then we introduce the definition of identity-based matchmaking encryption presented in [3].

### 3.1 Identity-Based Encryption

In the IBE setting, a functionality $\hat{F}$ is defined over a key space and an index space using sets of identities. The key space $\mathcal{K}$ and index space $\mathcal{I}$ for IBE then corresponds to all identities id. Here

$$
\hat{F}\left(\mathrm{id},\left(\mathrm{id}^{\prime}, m\right)\right):= \begin{cases}m & \text { if }^{\prime} \mathrm{id}^{\prime}=\mathrm{id} \\ \perp & \text { otherwise }\end{cases}
$$

An Identity-Based Encryption [7] scheme consists of following four algorithms: Setup, KeyGen, Enc, and Dec.
$-\operatorname{Setup}(\lambda) \rightarrow(p p, m k)$ : The setup algorithm takes in the security parameter $\lambda$, and outputs the public parameters $p p$, and the master key $m k$.

- KeyGen $(p p, m k, \mathrm{id}) \rightarrow s k_{\mathrm{id}}$ : The key generation algorithm takes in the public parameters $p p$, the master key $m k$, an identity id and produces a secret key $s k_{\text {id }}$ for that identity.
- Enc $(p p, \mathrm{id}, m) \rightarrow c t_{\mathrm{id}}$ : The encryption algorithm takes in the public parameters $p p$, an identity id, a message $m$ and outputs a ciphertext $c t_{\text {id }}$ encrypted under that identity.
$-\operatorname{Dec}\left(p p, s k_{\mathrm{id}}, c t_{\mathrm{id}}\right) \rightarrow m$ : The decryption algorithm takes in a secret key $s k_{\mathrm{id}}$, and a ciphertext $c t_{\mathrm{id}}$, and outputs the message $m$ when the $c t_{\mathrm{id}}$ is encrypted under the same id.

The security notion of anonymous IBE was formalized by [1], which is defined by the following game, played by a challenger $\mathcal{B}$ and an adversider $\mathcal{A}$.

- Setup: The challenger $\mathcal{B}$ runs the setup algorithm to generate $p p$ and $m k$. It gives $p p$ to the adversary $\mathcal{A}$.
- Phase 1: The adversary $\mathcal{A}$ adaptively requests key for identities id, and is provided with corresponding secret key $s k_{\text {id }}$, which the challenger $\mathcal{B}$ generates by running the key generation algorithm.
- Challenge: The adversary $\mathcal{A}$ gives $\mathcal{B}$ two challenge pairs ( $m_{0}, \mathrm{id}_{0}^{*}$ ) and ( $m_{1}, \mathrm{id}_{1}^{*}$ ). The challenge identities must not have been queried in Phase 1. The challenger $\mathcal{B}$ sets $\beta \in\{0,1\}$ randomly, and encrypts $m_{\beta}$ under $\mathrm{id}_{\beta}^{*}$ by running the encryption algorithm. It send the ciphertext to the adversary $\mathcal{A}$.
- Phase 2: This is the same as Phase 1 with the added restriction a secret key for $\mathrm{id}_{0}^{*}$, $\mathrm{id}_{1}^{*}$ cannot be requested.
- Guess: The adversary $\mathcal{A}$ must output a guess $\beta^{\prime}$ for $\beta$.

The advantage $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{IBE}}(\lambda)$ of an adversary $\mathcal{A}$ is defined to be $\operatorname{Pr}\left[\beta^{\prime}=\beta\right]-1 / 2$.
Definition 5. An Identity-Based Encryption scheme is secure and anonymous if all PPT adversaries achieve at most a negligible advantage in the above security game.

Remark 1: The security notion of non-anonymous IBE is defined as above with restriction that $\mathrm{id}_{0}^{*}=\mathrm{id}_{1}^{*}$.

### 3.2 Signature Schemes

A signature scheme is made up of three algorithms, (KeyGen, Sign, Verify) for generating keys, signing, and verifying signatures, respectively.

- KeyGen $\left(1^{\lambda}\right)$ : The key generation algorithm takes in the security parameter $1^{\lambda}$, and outputs the public key $p k$, and the secret key $s k$.
- Sign $(s k, m)$ : The signing algorithm takes in the secret key $s k$ and a message $m$, and produces a signature $\sigma$ for this message.
- Verify $(p k, \sigma, m)$ : The verifying algorithm takes in the public key $p k$ and a signature pair $(\sigma, m)$, and outputs valid or invalid.

The standard notion of security for a signature scheme is called existential unforgeability under a chosen message attack [17], which is defined using the following game between a challenger $\mathcal{C}$ and an adversary $\mathcal{A}$.

- Setup: The challenger $\mathcal{C}$ runs the key generation algorithm to generate $p k$ and $s k$. It gives $p k$ to the adversary $\mathcal{A}$.
- Query : The adversary $\mathcal{A}$ adaptively requests for messages $m_{1}, \ldots, m_{\nu} \in$ $\{0,1\}^{*}$, and is provided with corresponding signatures $\sigma_{1}, \ldots, \sigma_{\nu}$ by running the sign algorithm Sign.
- Output : Eventually, the adversary $\mathcal{A}$ outputs a pair $(\sigma, m)$.

The advantage $\operatorname{Adv}_{\mathcal{A}}{ }_{\mathcal{S i g}}(\lambda)$ of an adversary $\mathcal{A}$ is defined to be the probability that $\mathcal{A}$ wins in the above game, namely
(1) $m$ is not any of $m_{1}, \ldots, m_{\nu}$;
(2) Verify $(p k, \sigma, m)$ outputs valid.

Definition 6. A signature scheme is existentially unforgeable under an adaptive chosen message attack if all PPT adversaries achieve at most a negligible advantage in the above security game.

We assume that for any PPT algorithm $\mathcal{A}$, the probability that $\mathcal{A}$ wins in the above game is negligible in the security parameter $1^{\lambda}$. We note that the security of the signature scheme can follow from the security of IBE scheme by applying Naor's transform [7,8].

### 3.3 Syntax of IB-ME

In IB-ME, attributes and policies are treated as binary strings. We denote with rcv and snd the target identities or policies chosed by the sender and the receiver, respectively. We say that a match (resp. mismatch) occurs when $\sigma=$ snd and $\rho=\operatorname{rcv}$ (resp. $\sigma \neq$ snd or $\rho \neq \mathrm{rcv}$ ). The receiver can choose the target identity snd on the fly. More formally, an IB-ME scheme is composed of the following five polynomial-time algorithms:

- Setup $\left(1^{\lambda}\right) \rightarrow(m p k, m s k)$ : Upon input the security parameter $1^{\lambda}$, the randomized setup algorithm outputs the master public key $m p k$ and the master secret key $m s k$.
- SKGen $(m p k, m s k, \sigma) \rightarrow e k_{\sigma}$ : Upon input the master secret key $m s k$ and the identity $\sigma$, the randomized sender-key generator outputs an encryption key $e k_{\sigma}$ for $\sigma$.
- RKGen $(m p k, m s k, \rho) \rightarrow d k_{\rho}$ : Upon input the master secret key $m s k$ and the identity $\rho$, the randomized receiver-key generator outputs a decryption key $d k_{\rho}$ for $\rho$.
- Enc $\left(m p k, e k_{\sigma}, r c v, m\right) \rightarrow c t$ : Upon input the encryption key $e k_{\sigma}$ for identity $\sigma$, a target identity rcv and a message $m \in \mathcal{M}$, the randomized encryption algorithm produces a ciphertext $c t$ linked to both $\sigma$ and rcv.
- $\operatorname{Dec}\left(m p k, d k_{\rho}\right.$, snd, $\left.c t\right) \rightarrow m$ : Upon input the decryption key $d k_{\rho}$ for identity $\rho$, a target identity snd and a ciphertext $c t$, the deterministic decryption algorithm outputs either a message $m$ or $\perp$.

Correctness. Correctness of IB-ME simply says that in case of a match the receiver obtains the plaintext.

Definition 7 (Correctness of IB-ME). An IB-ME scheme $\Pi=$ (Setup, SKGen, RKGen, Enc, Dec) is correct if $\forall \lambda \in \mathbb{N}, \forall(m p k, m s k)$ output by $\operatorname{Setup}\left(1^{\lambda}\right), \forall m \in$ $\mathcal{M}, \forall \sigma, \rho, \mathrm{rcv}$, snd $\in\{0,1\}^{*}$ such that $\sigma=$ snd and $\rho=\mathrm{rcv}$ :

$$
\operatorname{Pr}\left[\operatorname{Dec}\left(d k_{\rho}, \operatorname{snd}, \operatorname{Enc}\left(e k_{\sigma}, \operatorname{rcv}, m\right)\right)=m\right] \geq 1-\operatorname{negl}(\lambda),
$$

where $e k_{\sigma} \stackrel{R}{\leftarrow} \operatorname{SKGen}(m s k, \sigma)$ and $d k_{\rho} \stackrel{R}{\leftarrow} \operatorname{RKGen}(m s k, \rho)$.

### 3.4 Security of IB-ME

We now define privacy and authenticity of IB-ME. Recall that privacy captures secrecy of the sender's inputs ( $\sigma, \mathrm{rcv}, m$ ). This is formalized by asking the adversary to distinguish between $\operatorname{Enc}\left(e k_{\sigma_{0}}, \mathrm{rcv}_{0}, m_{0}\right)$ and $\operatorname{Enc}\left(e k_{\sigma_{1}}, \mathrm{rcv}_{1}, m_{1}\right)$ where $\left(m_{0}, m_{1}, \sigma_{0}, \sigma_{1}, \mathrm{rcv}_{0}, \mathrm{rcv}_{1}\right)$ are chosen by the attacker. The definition of authenticity intuitively says that an adversary cannot compute a valid ciphertext under the identity $\sigma$, if it does not hold the corresponding encryption key $e k_{\sigma}$ produced by the challenger.

Fig.2. Games defining privacy and authenticity security of IB-ME. Oracles $\mathrm{O}_{1}, \mathrm{O}_{2}$ are implemented by SKGen(msk, $\left.\cdot\right)$, RKGen (msk, $\cdot$ ).

Definition 8 (Privacy of IB-ME). We say that an IB-ME $\Pi$ satisfies privacy if for all valid PPT adversaries $\mathcal{A}=\left(\mathrm{A}_{1}, \mathrm{~A}_{2}\right)$ :

$$
\left|\operatorname{Pr}\left[\mathbf{G}_{\Pi, \mathrm{A}}^{\mathrm{ib}-\text { priv }}(\lambda)=1\right]-\frac{1}{2}\right| \leq \operatorname{neg}(\lambda)
$$

where game $\mathbf{G}_{\Pi, \mathrm{A}}^{\text {ib-priv }}(\lambda)$ is depicted in Fig.2. Adversary $\mathcal{A}$ is called valid if $\forall \rho \in$ $\mathcal{Q}_{\mathrm{O}_{2}}$ it satisfies the following invariant:
(Mismatch condition) : $\rho \neq \operatorname{rcv}_{0} \wedge \rho \neq \operatorname{rcv}_{1}$.
Definition 9 (Authenticity of IB-ME). We say that an IB-ME $\Pi$ satisfies authenticity if for all valid PPT adversaries $\mathcal{A}$ :

$$
\operatorname{Pr}\left[\mathbf{G}_{I, \mathrm{~A}}^{\text {ib-auth }}(\lambda)=1\right] \leq \operatorname{negl}(\lambda)
$$

where game $\mathbf{G}_{\Pi, \mathrm{A}}^{\mathrm{ib}-\mathrm{a} t \mathrm{th}}(\lambda)$ is depicted in Fig. 2.
Definition 10 (Secure IB-ME). We say that an $I B-M E \Pi$ is secure if it satisfies privacy (Def.8) and authenticity (Def.9).

## 4 The Proposed IB-ME Construction

We are now ready to give the concrete construction of our IB-ME scheme.

### 4.1 Construction

$-\operatorname{Setup}\left(1^{\lambda}\right) \rightarrow(m p k, m s k)$ : This algorithm takes in the security parameter $1^{\lambda}$ and generates a bilinear pairing $\mathbb{G}:=\left(q, G_{1}, G_{2}, G_{T}, g_{1}, g_{2}, e\right)$ for sufficiently large prime order $q$. The algorithm samples random dual orthonormal bases $\left(\mathbb{D}, \mathbb{D}^{*}\right) \stackrel{R}{\leftarrow} \operatorname{Dual}\left(\mathbb{Z}_{q}^{8}\right)$. Let $\mathbf{d}_{\mathbf{1}}, \ldots, \mathbf{d}_{\mathbf{8}}$ denote the elements of $\mathbb{D}$ and $\mathbf{d}_{\mathbf{1}}^{*}, \ldots, \mathbf{d}_{\mathbf{8}}^{*}$ denote the elements of $\mathbb{D}^{*}$. Let $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{\mathbf{1}}^{*}}$. It also picks $\alpha, \eta \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and outputs the master public key as

$$
m p k:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{\mathbf{2}}}\right\}
$$

and the master secret key

$$
m s k:=\left\{\alpha, \eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{\mathbf{2}}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\} .
$$

- SKGen $(m p k, m s k, \sigma) \rightarrow e k_{\sigma}$ : This algorithm picks $r \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$. The encryption key is computed as

$$
e k_{\sigma}:=g_{1}^{\eta \mathbf{d}_{\mathbf{3}}+r\left(\sigma \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{4}\right)} .
$$

$-\operatorname{RKGen}(m p k, m s k, \rho) \rightarrow d k_{\rho}$ : This algorithm picks $s, s_{1}, s_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$. The decryption key is computed as

$$
d k_{\rho}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{d}_{1}^{*}+s_{1}\left(\rho \mathbf{d}_{\mathbf{1}}^{*}-\mathbf{d}_{\mathbf{2}}^{*}\right)+s \mathbf{d}_{\mathbf{3}}^{*}}, k_{2}=g_{2}^{s_{2}\left(\rho \mathbf{d}_{\mathbf{1}}^{*}-\mathbf{d}_{\mathbf{2}}^{*}\right)+s \mathbf{d}_{\mathbf{4}}^{*}}, k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\} .
$$

$-\operatorname{Enc}\left(m p k, e k_{\sigma}, \mathrm{rcv}, m\right) \rightarrow c t$ : This algorithm picks $z \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms the ciphertext as

$$
c t:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\alpha}\right)^{z}, \mathrm{C}_{0}=e k_{\sigma} \cdot g_{1}^{z\left(\mathbf{d}_{1}+\mathrm{rcvd}_{2}\right)}\right\} .
$$

- $\operatorname{Dec}\left(m p k, d k_{\rho}\right.$, snd, $\left.c t\right) \rightarrow m$ : This algorithm computes the message as

$$
m:=\frac{\mathrm{C}}{e\left(\mathrm{C}_{0}, k_{1} \cdot k_{2}^{\text {snd }}\right) \cdot k_{3}^{-1}} .
$$

Correctness: Correctness follows when snd $=\sigma$ and $\mathrm{rcv}=\rho$ :

$$
\begin{aligned}
& e\left(\mathrm{C}_{0}, k_{1} \cdot k_{2}^{\text {snd }}\right) \\
& =e\left(g_{1}^{\eta \mathbf{d}_{3}+r\left(\sigma \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{4}\right)+z\left(\mathbf{d}_{\mathbf{1}}+\mathrm{rcvd}_{2}\right)}, g_{2}^{\alpha \mathbf{d}_{1}^{*}+\left(s_{1}+s_{2} \cdot \text { snd }\right)\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{\mathbf{2}}^{*}\right)+s\left(\mathbf{d}_{\mathbf{3}}^{*}+\text { sndd }_{4}^{*}\right)}\right) \\
& =e\left(g_{1}, g_{2}\right)^{\eta s \mathbf{d}_{3} \cdot \mathbf{d}_{\mathbf{3}}^{*}+r s\left(\sigma \mathbf{d}_{\mathbf{3}} \cdot \mathbf{d}_{\mathbf{3}}^{*}-\operatorname{sndd}_{4} \cdot \mathbf{d}_{\mathbf{4}}^{*}\right)+\alpha z \mathbf{d}_{\mathbf{1}} \cdot \mathbf{d}_{\mathbf{1}}^{*}+z\left(s_{1}+s_{2} \cdot \mathrm{snd}^{2}\left(\rho \mathbf{d}_{1} \cdot \mathbf{d}_{\mathbf{1}}^{*}-\mathrm{rcvd} \mathbf{d}_{\mathbf{2}} \cdot \mathbf{d}_{\mathbf{2}}^{*}\right)\right.} \\
& =e\left(g_{1}, g_{2}\right)^{\eta s \mathbf{d}_{3} \cdot \mathbf{d}_{\mathbf{3}}^{*}+\alpha z \mathbf{d}_{1} \cdot \mathbf{d}_{\mathbf{1}}^{*}}=\left(g_{T}\right)^{\eta s+\alpha z}
\end{aligned}
$$

$$
\frac{\mathrm{C}}{e\left(\mathrm{C}_{0}, k_{1} \cdot k_{2}^{\text {snd }}\right) \cdot k_{3}^{-1}}=\frac{m \cdot\left(g_{T}^{\alpha}\right)^{z}}{\left(g_{T}\right)^{\eta s+\alpha z} \cdot g_{T}^{-\eta s}}=m
$$

### 4.2 Security Analysis

As for security, it can be proved that our proposed IB-ME scheme is secure (Def. 10) according to the Theorem 1 and Theorem 2, namely satisfies privacy (Def. 8) and authenticity (Def. 9) simultaneously.

Theorem 1. The proposed IB-ME scheme satisfies privacy under the Symmetric External Diffie-Hellman assumption. More precisely, for any PPT adversary $\mathcal{A}$ breaks the privacy property of our $I B-M E$ scheme, there exist probabilistic algorithms $\mathcal{B}_{0}, \mathcal{B}_{1,1}, \mathcal{B}_{1,2}, \ldots, \mathcal{B}_{\nu, 1}, \mathcal{B}_{\nu, 2}$ whose running times are essentially the same as that of $\mathcal{A}$, such that

$$
\operatorname{Adv}_{\mathcal{A}}^{\mathrm{IB}-\mathrm{ME}}(\lambda) \leq \operatorname{Adv}_{\mathcal{B}_{0}}^{\mathrm{DDH} 1}(\lambda)+\sum_{\kappa=1}^{\nu}\left(\operatorname{Adv}_{\mathcal{B}_{\kappa, 1}}^{\mathrm{DDH} 2}(\lambda)+\operatorname{Adv}_{\mathcal{B}_{\kappa, 2}}^{\mathrm{DDH} 2}(\lambda)\right)+(12 \nu+3) / q
$$

where $\nu$ is the maximum number of $\mathcal{A}$ 's key queries.

Proof Outline: There are many similarities between the proof of our scheme and the anonymous IBE scheme in [11]. We will follow a similar strategy of proving fully secure anonymous IBE, adopting the dual system encryption methodology by Waters [31] to prove that our IB-ME satisfies privacy under the SXDH assumption. The hardest part of the security proof is how to prove the negligible gap between two different forms of $d k_{\rho}$, especially when it is composed of three different keys $k_{1}, k_{2}$ and $k_{3}$. In order to solve this problem, apart from the concepts of semi-functional ciphertexts and semi-functional keys in our proof, we introduce the concept of inter-semi-functional secret key and provide algorithms that generate them. More precisely, inter-semi-functional key means that $k_{1}$ is semi-functional and $k_{2}$ is normal, while semi-functional key means that both $k_{1}$ and $k_{2}$ are semi-functional, and $k_{3}$ always remains the same. We note that these algorithms are only provided in a sequence of security games for the proof, and are not part of the IB-ME scheme. In particular, they do not need to be efficiently computable from the master public key and the master secret key. Meanwhile, another $\nu$ games are added into the proof, and for $\kappa$ from 1 to $\nu$, all the decryption keys will be converted into semi-functional keys step by step according to the sequence of changing normal key to inter-semi-functional key first in Game $_{\kappa, 1}$ and then changing it to semi-functional key in Game ${ }_{\kappa, 2}$. In other words, we consider $k_{1}$ and $k_{2}$ in $d k_{\rho}$ as two independent keys and generate their semi-functional keys in the KeyGenSF algorithm respectively. We first require that the challenger can simulate the two different forms of $k_{1}$, and then require it can simulate the two different forms of $k_{2}$ with the adversary. Then, we adopt the same procedure as in the security model definition, treating the output of SKGen algorithm as a part of the input to Enc algorithm, from which the corresponding semi-functional ciphertext is generated.

KeyGenSF: The algorithm picks $s, s_{1}, s_{2},\left\{s_{i, 1}\right\}_{i=5, \ldots, 8} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms the inter-semi-functional secret key as

$$
\begin{gather*}
\mathrm{d}_{\rho}^{(\text {inter-SF })}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{d}_{1}^{*}+s_{1}\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{2}^{*}\right)+s \mathbf{d}_{3}^{*}+\left[s_{5,1} \mathbf{d}_{5}^{*}+s_{6,1} \mathbf{d}_{6}^{*}+s_{7,1} \mathbf{d}_{\mathbf{7}}^{*}\right]}\right. \\
\left.k_{2}=g_{2}^{s_{2}\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{2}^{*}\right)+s \mathbf{d}_{4}^{*}}, k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\} \tag{1}
\end{gather*}
$$

The algorithm picks $s, s_{1}, s_{2},\left\{s_{i, j}\right\}_{i=5, \ldots, 8 ; j=1,2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms the semi-functional secret key as

$$
\begin{align*}
\mathrm{dk}_{\rho}^{(\mathrm{SF})}:=\left\{k_{1}\right. & =g_{2}^{\alpha \mathbf{d}_{1}^{*}+s_{1}\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{2}^{*}\right)+s \mathbf{d}_{3}^{*}+\left[s_{5,1} \mathbf{d}_{5}^{*}+s_{6,1} \mathbf{d}_{6}^{*}+s_{7,1} \mathbf{d}_{7}^{*}\right]}, \\
& \left.k_{2}=g_{2}^{s_{2}\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{2}^{*}\right)+s \mathbf{d}_{4}^{*}+\left[s_{5,2} \mathbf{d}_{5}^{*}+s_{6,2} \mathbf{d}_{6}^{*}+s_{8,2} \mathbf{d}_{8}^{*}\right]}, k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\} . \tag{2}
\end{align*}
$$

Hereafter we will ignore $k_{3}$ since it is always correctly generated.
EncryptSF: The algorithm picks $z, r, r_{5}, r_{6}, r_{7}, r_{8} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms a semifunctional ciphertext as

$$
\begin{gather*}
e k_{\sigma}:=g_{1}^{\eta \mathbf{d}_{\mathbf{3}}+r\left(\sigma \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{\mathbf{4}}\right)} \\
\mathrm{CT}_{e k_{\sigma}, \mathrm{rcv}}^{(\mathrm{SF})}:=\left\{\mathrm{C}:=m \cdot\left(g_{T}^{\alpha}\right)^{z}, \mathrm{C}_{0}:=e k_{\sigma} \cdot g_{1}^{z\left(\mathbf{d}_{\mathbf{1}}+\mathrm{rcvd}_{\mathbf{2}}\right)+\left[r_{5} \mathbf{d}_{\mathbf{5}}+r_{6} \mathbf{d}_{\mathbf{6}}+r_{7} \mathbf{d}_{\mathbf{7}}+r_{8} \mathbf{d}_{\mathbf{8}}\right]}\right. \\
\left.=g_{1}^{\eta \mathbf{d}_{\mathbf{3}}+r\left(\sigma \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{\mathbf{4}}\right)+z\left(\mathbf{d}_{\mathbf{1}}+\mathrm{rcvd}_{\mathbf{2}}\right)+\left[r_{5} \mathbf{d}_{\mathbf{5}}+r_{6} \mathbf{d}_{\mathbf{6}}+r_{7} \mathbf{d}_{\mathbf{7}}+r_{8} \mathbf{d}_{\mathbf{8}}\right]}\right\} \tag{3}
\end{gather*}
$$

Hereafter we will ignore $C$ since it is always correctly generated. We observe that if one applies the decryption procedure with a (inter) semi-functional key and a normal ciphertext, decryption will succeed because $\left(\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}\right)$ are orthogonal to all of the vectors in exponent of $C_{0}$, and hence have no effect on decryption. Similarly, decryption of a semi-functional ciphertext by a normal key will also succeed because $\left(\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}\right)$ are orthogonal to all of the vectors in the exponent of the key. When both the ciphertext and key are semi-functional, the result of decryption procedure $e\left(\mathrm{C}_{0}, k_{1} \cdot k_{2}^{\text {snd }}\right) \cdot k_{3}^{-1}$ will have an additional term, namely

$$
\begin{gathered}
e\left(g_{1}, g_{2}\right)^{r_{5}\left(s_{5,1}+\text { snd } \cdot s_{5,2}\right) \mathbf{d}_{\mathbf{5}} \cdot \mathbf{d}_{\mathbf{5}}^{*}+r_{6}\left(s_{6,1}+\text { snd } \cdot s_{6,2}\right) \mathbf{d}_{\mathbf{6}} \cdot \mathbf{d}_{\mathbf{6}}^{*}+r_{7} s_{7,1} \mathbf{d}_{\mathbf{7}} \cdot \mathbf{d}_{\mathbf{7}}^{*}+r_{8} \cdot \text { snd } \cdot s_{8,2} \mathbf{d}_{\mathbf{8}} \cdot \mathbf{d}_{\mathbf{8}}^{*}} \\
=g_{T}^{\left(r_{5} s_{5,1}+r_{6} s_{6,1}+r_{7} s_{7,1}\right)+\operatorname{snd}\left(r_{5} s_{5,2}+r_{6} s_{6,2}+r_{8} s_{8,2}\right)}
\end{gathered}
$$

Decryption will then fail unless $r_{5} s_{5,1}+r_{6} s_{6,1}+r_{7} s_{7,1} \equiv 0(\bmod q)$ and $r_{5} s_{5,2}+$ $r_{6} s_{6,2}+r_{8} s_{8,2} \equiv 0(\bmod q)$. If this modular equation holds, we say that this key and ciphertext pair is nominally semi-functional.

For a probabilistic polynomial-time adversary $\mathcal{A}$ which makes $\nu$ key queries $\mathrm{rcv}_{1}, \ldots, \mathrm{rcv}_{\nu}$, our proof of security consists of the following sequence of games between $\mathcal{A}$ and a challenger $\mathcal{B}$.

- Game ${ }_{\text {Real }}$ : is the real security game.
- Game 0 : is the same as Game Real except that the challenge ciphertext is semifunctional.
- Game $\kappa, 1$ : for $\kappa$ from 1 to $\nu$, Game $_{\kappa, 1}$ is the same as Game $_{0}$ except that the first $\kappa$ - 1 keys are semi-functional, the $\kappa$-th key is inter-semi-functional and the remaining keys are normal.
- Game $\kappa_{\kappa, 2}$ : for $\kappa$ from 1 to $\nu$, Game $_{\kappa, 2}$ is the same as Game ${ }_{0}$ except that the first $\kappa$ keys are semi-functional and the remaining keys are normal.
- Game ${ }_{\text {Final }}$ : is the same as $\mathrm{Game}_{\nu, 2}$, except that the challenge ciphertext is a semi-functional encryption of a random message in $G_{T}$ and under two random identities in $\mathbb{Z}_{q}$. We denote the challenge ciphertext in Game Final as $\mathrm{CT}_{e k_{\sigma_{\mathrm{R}}}, \mathrm{rcv}_{\mathrm{R}}}^{(\mathrm{R})}$.

We prove following lemmas to show the above games are indistinguishable by following an analogous strategy of $[12,18,19]$. Our main arguments are computational indistinguishability (guaranteed by the Subspace assumptions, which are implied by the SXDH assumption) and statistical indistinguishability. The advantage gap between $\mathrm{Game}_{\text {Real }}$ and $\mathrm{Game}_{0}$ is bounded by the advantage of the Subspace assumption in $G_{1}$. Additionally, we require a statistical indistinguishability argument to show that the distribution of the challenge ciphertext remains the same from the adversary's view. For $\kappa$ from 1 to $\nu$, the advantage gaps between Game $\kappa_{\kappa-1,2}$ and Game $\kappa_{\kappa, 1}$, and between Game ${ }_{\kappa, 1}$ and Game ${ }_{\kappa, 2}$ are bounded by the advantage of Subspace assumption in $G_{2}$. Similarly, we require a statistical indistinguishability argument to show that the distribution of the the $\kappa$-th semi-functional key remains the same from the adversary's view. Finally, we statistically transform $\mathrm{Game}_{\nu, 2}$ to $\mathrm{Game}_{\text {Final }}$ in one step, i.e., we show the joint distributions of

$$
\left(\mathrm{mpk}, \mathrm{CT}_{e k_{\sigma_{\beta}^{*}}^{*}, \mathrm{rcv}}^{\beta}(\mathrm{SF}),\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right) \quad \text { and } \quad\left(\mathrm{mpk}^{\mathrm{Cl}} \mathrm{CT}_{e k_{\sigma_{R}}, \mathrm{rcv}}^{(\mathrm{R})},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

are equivalent for the adversary's view.
We let $\operatorname{Adv}_{\mathcal{A}}^{\text {Game Real }^{( }}$denote an adversary $\mathcal{A}$ 's advantage in the real game.
Lemma 3. Suppose that there exists an adversary $\mathcal{A}$ where $\mid \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Real }}}(\lambda)-$ $\operatorname{Adv}_{\mathcal{A}}^{\mathrm{Game}_{0}}(\lambda) \mid=\epsilon$. Then there exists an algorithm $\mathcal{B}_{0}$ such that $\operatorname{Adv}_{\mathcal{B}_{0}}^{\mathrm{DS} 1}(\lambda)=$ $\epsilon-2 / q$, with $K=4$ and $N=8$.

Proof. $\mathcal{B}_{0}$ is given

$$
D:=\left(\mathbb{G} ; g_{2}^{\mathbf{b}_{1}^{*}}, g_{2}^{\mathbf{b}_{\mathbf{*}}^{*}}, g_{2}^{\mathbf{b}_{3}^{*}}, g_{2}^{\mathbf{b}_{4}^{*}}, g_{1}^{\mathbf{b}_{1}}, \ldots, g_{1}^{\mathbf{b}_{8}}, U_{1}, U_{2}, U_{3}, U_{4}, \mu_{2}\right)
$$

along with $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. And in $D$ we have that $U_{1}=g_{2}^{\mu_{1} \mathbf{b}_{1}^{*}+\mu_{2} \mathbf{b}_{5}^{*}}, U_{2}=$ $g_{2}^{\mu_{1} \mathbf{b}_{2}^{*}+\mu_{2} \mathbf{b}_{\mathbf{6}}^{*}}, U_{3}=g_{2}^{\mu_{1} \mathbf{b}_{3}^{*}+\mu_{2} \mathbf{b}_{7}^{*}}, U_{4}=g_{2}^{\mu_{1} \mathbf{b}_{4}^{*}+\mu_{2} \mathbf{b}_{8}^{*}}$. We require that $\mathcal{B}_{0}$ decides whether $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are distributed as
$\left(g_{1}^{\tau_{1} \mathbf{b}_{1}}, g_{1}^{\tau_{1} \mathbf{b}_{2}}, g_{1}^{\tau_{1} \mathbf{b}_{3}}, g_{1}^{\tau_{1} \mathbf{b}_{4}}\right) \quad$ or $\quad\left(g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{5}}, g_{1}^{\tau_{1} \mathbf{b}_{2}+\tau_{2} \mathbf{b}_{6}}, g_{1}^{\tau_{1} \mathbf{b}_{3}+\tau_{2} \mathbf{b}_{7}}, g_{1}^{\tau_{1} \mathbf{b}_{4}+\tau_{2} \mathbf{b}_{8}}\right)$.
$\mathcal{B}_{0}$ simulates $G_{\text {ame }}$ Real or $G a m e_{0}$ with $\mathcal{A}$ depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. To compute the master public key and master secret key, $\mathcal{B}_{0}$
chooses a random invertible matrix $\mathbf{A} \in \mathbb{Z}_{q}^{4 \times 4}$. We then implicitly set dual orthonormal bases $\mathbb{D}, \mathbb{D}^{*}$ to:

$$
\begin{aligned}
& \mathbf{d}_{1}:=\mathbf{b}_{1}, \ldots, \mathbf{d}_{4}:=\mathbf{b}_{4}, \quad\left(\mathbf{d}_{5}, \ldots, \mathbf{d}_{8}\right):=\left(\mathbf{b}_{5}, \ldots, \mathbf{b}_{8}\right) \mathbf{A} \\
& \mathbf{d}_{1}^{*}:=\mathbf{b}_{1}^{*}, \ldots, \mathbf{d}_{4}^{*}:=\mathbf{b}_{4}^{*}, \quad\left(\mathbf{d}_{5}^{*}, \ldots, \mathbf{d}_{8}^{*}\right):=\left(\mathbf{b}_{5}^{*}, \ldots, \mathbf{b}_{8}^{*}\right)\left(\mathbf{A}^{-1}\right)^{\top} .
\end{aligned}
$$

We note that $\mathbb{D}, \mathbb{D}^{*}$ are properly distributed, and reveal no information about A. Moreover, $\mathcal{B}_{0}$ cannot generate $g_{2}^{\mathbf{d}_{5}^{*}}, g_{2}^{\mathbf{d}_{6}^{*}}, g_{2}^{\mathbf{d}_{7}^{*}}, g_{2}^{\mathbf{d}_{8}^{*}}$, but these will not be needed for creating normal keys. $\mathcal{B}_{0}$ chooses random value $\alpha, \eta \in \mathbb{Z}_{q}$ and computes $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{1}^{*}}$. It then gives $\mathcal{A}$ the master public key

$$
\mathrm{mpk}:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{\mathbf{2}}}\right\} .
$$

The master secret key

$$
\mathrm{msk}:=\left\{\alpha, \eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}
$$

is known to $\mathcal{B}_{0}$, which allows $\mathcal{B}_{0}$ to respond to all of $\mathcal{A}$ 's key queries by calling the normal key generation algorithm.
$\mathcal{A}$ sends $\mathcal{B}_{0}$ two pairs $\left(m_{0}, \mathrm{rcv}_{0}^{*}, \sigma_{0}^{*}\right)$ and $\left(m_{1}, r \mathrm{rv}_{1}^{*}, \sigma_{1}^{*}\right) . \mathcal{B}_{0}$ chooses a random bit $\beta \in\{0,1\}$ and picks $r^{\prime} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and then encrypts $m_{\beta}$ under $\operatorname{rcv}_{\beta}^{*}$ and $e k_{\sigma_{\beta}^{*}}$ as follows:

$$
\begin{gathered}
e k_{\sigma_{\beta}^{*}}:=g_{1}^{\eta \mathbf{b}_{3}}\left(T_{3}^{\sigma_{\beta}^{*}} \cdot T_{4}^{-1}\right)^{r^{\prime}}, \\
\mathrm{C}:=m_{\beta} \cdot\left(e\left(T_{1}, g_{2}^{\mathbf{b}_{1}^{*}}\right)\right)^{\alpha}=m_{\beta} \cdot\left(g_{T}^{\alpha}\right)^{z}, \\
\mathrm{C}_{0}:=e k_{\sigma_{\beta}^{*}} \cdot T_{1} \cdot T_{2}^{\mathrm{rcv}}=g_{1}^{\eta \mathbf{b}_{3}}\left(T_{3}^{\sigma_{\beta}^{*}} \cdot T_{4}^{-1}\right)^{r^{\prime}} \cdot T_{1} \cdot T_{2}^{\mathrm{rcv}},
\end{gathered}
$$

where $\mathcal{B}_{0}$ has implicitly set $r:=r^{\prime} \tau_{1}$ and $z:=\tau_{1}$. It gives the ciphertext $c t=$ (C, $\mathrm{C}_{0}$ ) to $\mathcal{A}$.

Now, if ( $T_{1}, T_{2}, T_{3}, T_{4}$ ) are equal to ( $g_{1}^{\tau_{1} \mathbf{b}_{1}}, g_{1}^{\tau_{1} \mathbf{b}_{2}}, g_{1}^{\tau_{1} \mathbf{b}_{3}}, g_{1}^{\tau_{1} \mathbf{b}_{4}}$ ), then this is a properly distributed normal encryption of $m_{\beta}$. In this case, $\mathcal{B}_{0}$ has properly simulated Game ${ }_{\text {Real }}$. If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{5}}, g_{1}^{\tau_{1} \mathbf{b}_{2}+\tau_{2} \mathbf{b}_{6}}, g_{1}^{\tau_{1} \mathbf{b}_{3}+\tau_{2} \mathbf{b}_{7}}\right.$, $\left.g_{1}^{\tau_{1} \mathbf{b}_{4}+\tau_{2} \mathbf{b}_{8}}\right)$ instead, then the ciphertext element $\mathrm{C}_{0}$ has an additional term of

$$
\tau_{2}\left(\mathbf{b}_{\mathbf{5}}+\operatorname{rcv}_{\beta}^{*} \mathbf{b}_{\mathbf{6}}\right)+r^{\prime} \tau_{2}\left(\sigma_{\beta}^{*} \mathbf{b}_{\mathbf{7}}-\mathbf{b}_{\mathbf{8}}\right)
$$

in its exponent. The coefficients here in the basis $\mathbf{b}_{5}, \mathbf{b}_{6}, \mathbf{b}_{7}, \mathbf{b}_{8}$ form the vector $\tau_{2}\left(1, \mathrm{rcv}_{\beta}^{*}, r^{\prime} \sigma_{\beta}^{*},-r^{\prime}\right)$. To compute the coefficients in the basis $\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}$, we multiply the matrix $\mathbf{A}^{-1}$ by the transpose of this vector, obtaining the new vector $\tau_{2} \mathbf{A}^{-1}\left(1, \operatorname{rcv}_{\beta}^{*}, r^{\prime} \sigma_{\beta}^{*},-r^{\prime}\right)^{\top}$. Since $\mathbf{A}$ is random (everything else given to $\mathcal{A}$ has been distributed independently of $\mathbf{A}$ ), these coefficients are uniformly random except with probability $2 / q$ (namely, the cases $\tau_{2}$ defined in Subspace problem is zero, $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equation 3 is the zero vector) from Lemma 2. Therefore in this case, $\mathcal{B}_{0}$ has properly simulated Game ${ }_{0}$. This allows $\mathcal{B}_{0}$ to leverage $\mathcal{A}$ 's advantage $\epsilon$ between Game Real and Game $_{0}$ to achieve an advantage $\epsilon-\frac{2}{q}$ against the subspace assumption in $G_{1}$, namely $\operatorname{Adv}_{\mathcal{B}_{0}}^{\mathrm{DS} 1}(\lambda)=\epsilon-\frac{2}{q}$.

Lemma 4. Suppose that there exists an adversary $\mathcal{A}$ where $\mid \operatorname{Adv}_{\mathcal{A}} \operatorname{Game}_{\kappa-1,2}(\lambda)-$ $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\kappa, 1}}(\lambda) \mid=\epsilon$. Then there exists an algorithm $\mathcal{B}_{\kappa, 1}$ such that $\operatorname{Adv}_{\mathcal{B}_{\kappa, 1}}^{\operatorname{DS} 2}(\lambda)=$ $\epsilon-6 / q$, with $K=4$ and $N=8$.

Proof. $\mathcal{B}_{\kappa, 1}$ is given

$$
D:=\left(\mathbb{G} ; g_{1}^{\mathbf{b}_{1}}, g_{1}^{\mathbf{b}_{2}}, g_{1}^{\mathbf{b}_{3}}, g_{1}^{\mathbf{b}_{4}}, g_{2}^{\mathbf{b}_{1}^{*}}, \ldots, g_{2}^{\mathbf{b}_{8}^{*}}, U_{1}, U_{2}, U_{3}, U_{4}, \mu_{2}\right)
$$

along with $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. And in $D$ we have that $U_{1}=g_{1}^{\mu_{1} \mathbf{b}_{1}+\mu_{2} \mathbf{b}_{5}}, U_{2}=$ $g_{1}^{\mu_{1} \mathbf{b}_{2}+\mu_{2} \mathbf{b}_{6}}, U_{3}=g_{1}^{\mu_{1} \mathbf{b}_{3}+\mu_{2} \mathbf{b}_{7}}, U_{4}=g_{1}^{\mu_{1} \mathbf{b}_{4}+\mu_{2} \mathbf{b}_{8}}$. We require that $\mathcal{B}_{\kappa, 1}$ decides whether $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are distributed as
$\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right) \quad$ or $\quad\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$.
$\mathcal{B}_{\kappa, 1}$ simulates Game $_{\kappa-1,2}$ or Game $_{\kappa, 1}$ with $\mathcal{A}$ depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. To compute the master public key and master secret key, $\mathcal{B}_{\kappa, 1}$ chooses a random invertible matrix $\mathbf{A} \in \mathbb{Z}_{q}^{4 \times 4}$. We then implicitly set dual orthonormal bases $\mathbb{D}, \mathbb{D}^{*}$ to:

$$
\begin{aligned}
& \mathbf{d}_{1}:=\mathbf{b}_{1}, \ldots, \mathbf{d}_{4}:=\mathbf{b}_{4}, \quad\left(\mathbf{d}_{5}, \ldots, \mathbf{d}_{8}\right):=\left(\mathbf{b}_{5}, \ldots, \mathbf{b}_{8}\right) \mathbf{A} \\
& \mathbf{d}_{1}^{*}:=\mathbf{b}_{1}^{*}, \ldots, \mathbf{d}_{4}^{*}:=\mathbf{b}_{4}^{*}, \quad\left(\mathbf{d}_{5}^{*}, \ldots, \mathbf{d}_{8}^{*}\right):=\left(\mathbf{b}_{5}^{*}, \ldots, \mathbf{b}_{8}^{*}\right)\left(\mathbf{A}^{-1}\right)^{\top} .
\end{aligned}
$$

We note that $\mathbb{D}, \mathbb{D}^{*}$ are properly distributed, and reveal no information about A. $\mathcal{B}_{\kappa, 1}$ chooses random value $\alpha, \eta \in \mathbb{Z}_{q}$ and compute $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{1}^{*}}$. It then gives $\mathcal{A}$ the master public key

$$
\mathrm{mpk}:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}\right\}
$$

The master secret key

$$
\text { msk }:=\left\{\alpha, \eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}
$$

is known to $\mathcal{B}_{\kappa, 1}$, which allows $\mathcal{B}_{\kappa, 1}$ to respond to all of $\mathcal{A}$ 's key queries by calling the normal key generation algorithm. Since $\mathcal{B}_{\kappa, 1}$ also knows $g_{2}^{\mathbf{d}_{5}^{*}}, g_{2}^{\mathbf{d}_{6}^{*}}, g_{2}^{\mathbf{d}_{7}^{*}}, g_{2}^{\mathbf{d}_{8}^{*}}$, it can easily produce (inter) semi-functional keys. To answer the first $\kappa$ - 1 key queries that $\mathcal{A}$ makes, $\mathcal{B}_{\kappa, 1}$ runs the KeyGenSF algorithm to produce semifunctional keys and gives these to $\mathcal{A}$. To answer the $\kappa$-th key query for $\rho_{\kappa}$, $\mathcal{B}_{\kappa, 1}$ picks $s, s_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and responds with:

$$
\mathrm{dk}_{\rho_{\kappa}}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{b}_{1}^{*}+s \mathbf{b}_{3}^{*}} \cdot\left(T_{1}^{\rho_{\kappa}} T_{2}^{-1}\right), k_{2}=g_{2}^{s_{2}\left(\rho_{\kappa} \mathbf{b}_{1}^{*}-\mathbf{b}_{2}^{*}\right)+s \mathbf{b}_{4}^{*}}, k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\}
$$

Noting that $k_{2}$ is a normal key, $\mathcal{B}_{\kappa, 1}$ needs to determine whether $k_{1}$ is semifunctional or normal key and this implicitly sets $s_{1}:=\tau_{1}$. If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to ( $g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}$ ), then this is a properly distributed normal key.

If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to ( $\left.g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$, then this is a inter-semi-functional key, whose exponent vector includes

$$
\begin{equation*}
\tau_{2}\left(\rho_{\kappa} \mathbf{b}_{\mathbf{5}}{ }^{*}-\mathbf{b}_{\mathbf{6}}{ }^{*}+0 \cdot \mathbf{b}_{\mathbf{7}}{ }^{*}+0 \cdot \mathbf{b}_{\mathbf{8}}{ }^{*}\right) \tag{4}
\end{equation*}
$$

as its component in the span of $\mathbf{b}_{5}^{*}, \mathbf{b}_{6}^{*}, \mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$. To respond to the remaining key queries, $\mathcal{B}_{\kappa, 1}$ simply runs the normal key generation algorithm.

At some point, $\mathcal{A}$ sends $\mathcal{B}_{\kappa, 1}$ two pairs $\left(m_{0}, \mathrm{rcv}_{0}^{*}, \sigma_{0}^{*}\right)$ and $\left(m_{1}, \mathrm{rcv}_{1}^{*}, \sigma_{1}^{*}\right) . \mathcal{B}_{\kappa, 1}$ chooses a random bit $\beta \in\{0,1\}$ and picks $r^{\prime} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and then encrypts $m_{\beta}$ under $\operatorname{rcv}_{\beta}^{*}$ and $e k_{\sigma_{\beta}^{*}}$ as follows:

$$
\begin{gathered}
e k_{\sigma_{\beta}^{*}}:=g_{1}^{\eta \mathbf{b}_{3}}\left(U_{3}^{\sigma_{\beta}^{*}} \cdot U_{4}^{-1}\right)^{r^{\prime}}, \\
\mathrm{C}:=m_{\beta} \cdot\left(e\left(U_{1}, g_{2}^{\mathbf{b}_{1}^{*}}\right)\right)^{\alpha}=m_{\beta} \cdot\left(g_{T}^{\alpha}\right)^{z}, \\
\mathrm{C}_{0}:=e k_{\sigma_{\beta}^{*}} \cdot U_{1} \cdot U_{2}^{r \mathrm{rcv}}=g_{1}^{\eta \mathbf{b}_{3}}\left(U_{3}^{\sigma_{\beta}^{*}} \cdot U_{4}^{-1}\right)^{r^{\prime}} \cdot U_{1} \cdot U_{2}^{r c v_{\beta}^{*}},
\end{gathered}
$$

where $\mathcal{B}_{\kappa, 1}$ has implicitly set $r:=r^{\prime} \mu_{1}$ and $z:=\mu_{1}$. The "semi-functional part" of the exponent vector here is:

$$
\begin{equation*}
\mu_{2}\left(\mathbf{b}_{\mathbf{5}}+\operatorname{rcv}_{\beta}^{*} \mathbf{b}_{\mathbf{6}}\right)+r^{\prime} \mu_{2}\left(\sigma_{\beta}^{*} \mathbf{b}_{\mathbf{7}}-\mathbf{b}_{\mathbf{8}}\right) \tag{5}
\end{equation*}
$$

We observe that if $\operatorname{rcv}_{\beta}^{*}=\rho_{\kappa}$ (which is not allowed) and the decryption algorithm gives an attribute $\operatorname{snd}_{\kappa}$ that can correctly decrypt the ciphertext, i.e., $\operatorname{snd}_{\kappa}=$ $\sigma_{\beta}^{*}$, then vectors in Equations 4 and 5 would be orthogonal in the decryption algorithm, resulting in a nominally semi-functional ciphertext and key pair. It gives the ciphertext $c t=\left(\mathrm{C}, \mathrm{C}_{0}\right)$ to $\mathcal{A}$.

We now argue that since $\operatorname{rcv}_{\beta}^{*} \neq \rho_{\kappa}$, in $\mathcal{A}$ 's view the vectors in Equations 4 and 5 are distributed as random vectors in the spans of $\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ and $\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}$ respectively. To see this, we take the coefficients of vectors in Equations 4 and 5 in terms of the bases $\mathbf{b}_{5}^{*}, \mathbf{b}_{6}^{*}, \mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$ and $\mathbf{b}_{5}, \mathbf{b}_{6}, \mathbf{b}_{7}, \mathbf{b}_{8}$ respectively and translate them into coefficients in terms of the bases $\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ and $\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}$. Using the change of basis matrix $A$, we obtain the new coefficients (in vector form) as:

$$
\tau_{2} \mathbf{A}^{\top}\left(\rho_{\kappa},-1,0,0\right)^{\top}, \quad \mu_{2} \mathbf{A}^{-1}\left(1, \operatorname{rcv}_{\beta}^{*}, r^{\prime} \sigma_{\beta}^{*},-r^{\prime}\right)^{\top}
$$

Since the distribution of everything given to $\mathcal{A}$ except for the $\kappa$-th key and the challenge ciphertext is independent of the random matrix $\mathbf{A}$ and $\operatorname{rcv}_{\beta}^{*} \neq \rho_{\kappa}$, we can conclude that these coefficients are uniformly except with probability $4 / q$ (namely, the cases $\tau_{2}$ or $\mu_{2}$ defined in Subspace problem is zero, $\left\{s_{i, 1}\right\}_{i=5, \ldots, 8}$ or $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equations 1 and 3 is the zero vector) from Lemma 2. Thus, $\mathcal{B}_{\kappa, 1}$ has properly simulated Game $_{\kappa, 1}$ in this case.

If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right)$, then the coefficients of the vector in Equation 5 are uniformly except with probability $2 / q$ (namely,
the cases $\mu_{2}$ defined in Subspace problem is zero, $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equation 3 is the zero vector) from Lemma 2 . Thus, $\mathcal{B}_{\kappa, 1}$ has properly simulated Game $_{\kappa-1,2}$ in this case.

In summary, $\mathcal{B}_{\kappa, 1}$ has properly simulated either Game ${ }_{\kappa-1,2}$ or Game ${ }_{\kappa, 1}$ for $\mathcal{A}$, depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. It can therefore leverage $\mathcal{A}$ 's advantage $\epsilon$ between these games to obtain an advantage $\epsilon-6 / q$ against the Subspace assumption in $G_{2}$, namely $\operatorname{Adv}_{\mathcal{B}_{\kappa, 1}}^{\text {DS2 }}(\lambda)=\epsilon-6 / q$.

Lemma 5. Suppose that there exists an adversary $\mathcal{A}$ where $\mid \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\kappa, 1}}(\lambda)-$ $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\kappa, 2}}(\lambda) \mid=\epsilon$. Then there exists an algorithm $\mathcal{B}_{\kappa, 2}$ such that $\operatorname{Adv}_{\mathcal{B}_{\kappa, 2}}^{\mathrm{DS} 2}(\lambda)=$ $\epsilon-6 / q$, with $K=4$ and $N=8$.

Proof. This proof is very similar to the proof of the previous lemma and $\mathcal{B}_{\kappa, 2}$ is given

$$
D:=\left(\mathbb{G} ; g_{1}^{\mathbf{b}_{1}}, g_{1}^{\mathbf{b}_{2}}, g_{1}^{\mathbf{b}_{3}}, g_{1}^{\mathbf{b}_{4}}, g_{2}^{\mathbf{b}_{1}^{*}}, \ldots, g_{2}^{\mathbf{b}_{8}^{*}}, U_{1}, U_{2}, U_{3}, U_{4}, \mu_{2}\right)
$$

along with $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. And in $D$ we have that $U_{1}=g_{1}^{\mu_{1} \mathbf{b}_{1}+\mu_{2} \mathbf{b}_{\mathbf{5}}}, U_{2}=$ $g_{1}^{\mu_{1} \mathbf{b}_{\mathbf{2}}+\mu_{2} \mathbf{b}_{6}}, U_{3}=g_{1}^{\mu_{1} \mathbf{b}_{\mathbf{3}}+\mu_{2} \mathbf{b}_{7}}, U_{4}=g_{1}^{\mu_{1} \mathbf{b}_{4}+\mu_{2} \mathbf{b}_{\mathbf{8}}}$. We require that $\mathcal{B}_{\kappa, 2}$ decides whether $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are distributed as
$\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right) \quad$ or $\quad\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$.
$\mathcal{B}_{\kappa, 2}$ simulates Game ${ }_{\kappa, 1}$ or Game $_{\kappa, 2}$ with $\mathcal{A}$ depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. To compute the master public key and master secret key, $\mathcal{B}_{\kappa, 2}$ chooses a random invertible matrix $\mathbf{A} \in \mathbb{Z}_{q}^{4 \times 4}$. We then implicitly set dual orthonormal bases $\mathbb{D}, \mathbb{D}^{*}$ to:

$$
\begin{aligned}
& \mathbf{d}_{1}:=\mathbf{b}_{1}, \ldots, \mathbf{d}_{4}:=\mathbf{b}_{4}, \quad\left(\mathbf{d}_{5}, \ldots, \mathbf{d}_{8}\right):=\left(\mathbf{b}_{5}, \ldots, \mathbf{b}_{8}\right) \mathbf{A} \\
& \mathbf{d}_{1}^{*}:=\mathbf{b}_{1}^{*}, \ldots, \mathbf{d}_{4}^{*}:=\mathbf{b}_{4}^{*}, \quad\left(\mathbf{d}_{5}^{*}, \ldots, \mathbf{d}_{8}^{*}\right):=\left(\mathbf{b}_{5}^{*}, \ldots, \mathbf{b}_{8}^{*}\right)\left(\mathbf{A}^{-1}\right)^{\top} .
\end{aligned}
$$

We note that $\mathbb{D}, \mathbb{D}^{*}$ are properly distributed, and reveal no information about A. $\mathcal{B}_{\kappa, 2}$ chooses random value $\alpha, \eta \in \mathbb{Z}_{q}$ and compute $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{1}^{*}}$. It then gives $\mathcal{A}$ the master public key

$$
\mathrm{mpk}:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}\right\}
$$

The master secret key

$$
\text { msk }:=\left\{\alpha, \eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}
$$

is known to $\mathcal{B}_{\kappa, 2}$, which allows $\mathcal{B}_{\kappa, 2}$ to respond to all of $\mathcal{A}$ 's key queries by calling the normal key generation algorithm. Since $\mathcal{B}_{\kappa, 2}$ also knows $g_{2}^{\mathbf{d}_{5}^{*}}, g_{2}^{\mathbf{d}_{6}^{*}}, g_{2}^{\mathbf{d}_{7}^{*}}, g_{2}^{\mathbf{d}_{8}^{*}}$, it can easily produce (inter) semi-functional keys. To answer the first $\kappa$ - 1 key queries that $\mathcal{A}$ makes, $\mathcal{B}_{\kappa, 2}$ runs the KeyGenSF algorithm to produce semifunctional keys and gives these to $\mathcal{A}$. To answer the $\kappa$-th key query for $\rho_{\kappa}$,
$\mathcal{B}_{\kappa, 2}$ picks $s, s_{1},\left\{s_{i, 1}\right\}_{i=5, \ldots, 8} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and responds with:

$$
\begin{gathered}
\mathrm{dk}_{\rho_{\kappa}}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{d}_{1}^{*}+s_{1}\left(\rho \mathbf{d}_{1}^{*}-\mathbf{d}_{2}^{*}\right)+s \mathbf{d}_{\mathbf{3}}^{*}+\left[s_{5,1} \mathbf{d}_{5}^{*}+s_{6,1} \mathbf{d}_{6}^{*}+s_{7,1} \mathbf{d}_{7}^{*}\right]},\right. \\
\left.k_{2}=g_{2}^{s \mathbf{b}_{4}^{*}} \cdot\left(T_{1}^{\rho_{\kappa}} T_{2}^{-1}\right), \quad k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\} .
\end{gathered}
$$

Noting that $k_{1}$ is a semi-functional key, $\mathcal{B}_{\kappa, 2}$ needs to determine whether $k_{2}$ is semi-functional or normal key and this implicitly sets $s_{2}:=\tau_{1}$. If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right)$, then this is a properly distributed normal key. If ( $T_{1}, T_{2}, T_{3}, T_{4}$ ) are equal to ( $\left.g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$, then this is a semi-functional key, whose exponent vector includes

$$
\begin{equation*}
\tau_{2}\left(\rho_{\kappa} \mathbf{b}_{\mathbf{5}}{ }^{*}-\mathbf{b}_{\mathbf{6}}{ }^{*}+0 \cdot \mathbf{b}_{\mathbf{7}}{ }^{*}+0 \cdot \mathbf{b}_{\mathbf{8}}{ }^{*}\right) \tag{6}
\end{equation*}
$$

as its component in the span of $\mathbf{b}_{5}^{*}, \mathbf{b}_{6}^{*}, \mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$. To respond to the remaining key queries, $\mathcal{B}_{\kappa, 2}$ simply runs the normal key generation algorithm.

At some point, $\mathcal{A}$ sends $\mathcal{B}_{\kappa, 2}$ two pairs $\left(m_{0}, \mathrm{rcv}_{0}^{*}, \sigma_{0}^{*}\right)$ and $\left(m_{1}, \mathrm{rcv}_{1}^{*}, \sigma_{1}^{*}\right) . \mathcal{B}_{\kappa, 2}$ chooses a random bit $\beta \in\{0,1\}$ and picks $r^{\prime} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and then encrypts $m_{\beta}$ under $\operatorname{rcv}_{\beta}^{*}$ and $e k_{\sigma_{\beta}^{*}}$ as follows:

$$
\begin{gathered}
e k_{\sigma_{\beta}^{*}}:=g_{1}^{\eta \mathbf{b}_{3}}\left(U_{3}^{\sigma_{\beta}^{*}} \cdot U_{4}^{-1}\right)^{r^{\prime}} \\
\mathrm{C}:=m_{\beta} \cdot\left(e\left(U_{1}, g_{2}^{\mathbf{b}_{1}^{*}}\right)\right)^{\alpha}=m_{\beta} \cdot\left(g_{T}^{\alpha}\right)^{z}, \\
\mathrm{C}_{0}:=e k_{\sigma_{\beta}^{*}} \cdot U_{1} \cdot U_{2}^{\mathrm{rcc} v_{\beta}^{*}}=g_{1}^{\eta \mathbf{b}_{3}}\left(U_{3}^{\sigma_{\beta}^{*}} \cdot U_{4}^{-1}\right)^{r^{\prime}} \cdot U_{1} \cdot U_{2}^{\mathrm{rcv}}
\end{gathered}
$$

where $\mathcal{B}_{\kappa, 2}$ has implicitly set $r:=r^{\prime} \mu_{1}$ and $z:=\mu_{1}$. The "semi-functional part" of the exponent vector here is:

$$
\begin{equation*}
\mu_{2}\left(\mathbf{b}_{\mathbf{5}}+\operatorname{rcv}_{\beta}^{*} \mathbf{b}_{\mathbf{6}}\right)+r^{\prime} \mu_{2}\left(\sigma_{\beta}^{*} \mathbf{b}_{\mathbf{7}}-\mathbf{b}_{\mathbf{8}}\right) \tag{7}
\end{equation*}
$$

We observe that if $\operatorname{rcv}_{\beta}^{*}=\rho_{\kappa}$ (which is not allowed) and the decryption algorithm gives an attribute $\operatorname{snd}_{\kappa}$ that can correctly decrypt the ciphertext, i.e., snd $_{\kappa}=\sigma_{\beta}^{*}$, then vectors in Equations 6 and 7 would be orthogonal in the decryption algorithm, resulting in a nominally semi-functional ciphertext and key pair. It gives the ciphertext $c t=\left(\mathrm{C}, \mathrm{C}_{0}\right)$ to $\mathcal{A}$.

We now argue that since $\operatorname{rcv}_{\beta}^{*} \neq \rho_{\kappa}$, in $\mathcal{A}$ 's view the vectors in Equations 6 and 7 are distributed as random vectors in the spans of $\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ and $\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}$ respectively. To see this, we take the coefficients of vectors in Equations 6 and 7 in terms of the bases $\mathbf{b}_{5}^{*}, \mathbf{b}_{6}^{*}, \mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$ and $\mathbf{b}_{5}, \mathbf{b}_{6}, \mathbf{b}_{7}, \mathbf{b}_{8}$ respectively and translate them into coefficients in terms of the bases $\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ and $\mathbf{d}_{5}, \mathbf{d}_{6}, \mathbf{d}_{7}, \mathbf{d}_{8}$. Using the change of basis matrix $A$, we obtain the new coefficients (in vector form) as:

$$
\tau_{2} \mathbf{A}^{\top}\left(\rho_{\kappa},-1,0,0\right)^{\top}, \quad \mu_{2} \mathbf{A}^{-1}\left(1, \operatorname{rcv}_{\beta}^{*}, r^{\prime} \sigma_{\beta}^{*},-r^{\prime}\right)^{\top}
$$

Since the distribution of everything given to $\mathcal{A}$ except for the $\kappa$-th key and the challenge ciphertext is independent of the random matrix $\mathbf{A}$ and $\operatorname{rcv}_{\beta}^{*} \neq \rho_{\kappa}$, we
can conclude that these coefficients are uniformly except with probability $4 / q$ (namely, the cases $\tau_{2}$ or $\mu_{2}$ defined in Subspace problem is zero, $\left\{s_{i, j}\right\}_{i=5, \ldots, 8 ; j=1,2}$ or ( $r_{5}, r_{6}, r_{7}, r_{8}$ ) defined in Equations 2 and 3 is the zero vector) from Lemma 2. Thus, $\mathcal{B}_{\kappa, 2}$ has properly simulated Game $_{\kappa, 2}$ in this case.

If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right)$, then the coefficients of the vector in Equation 7 are uniformly except with probability $2 / q$ (namely, the cases $\mu_{2}$ defined in Subspace problem is zero, $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equation 3 is the zero vector) from Lemma 2 . Thus, $\mathcal{B}_{\kappa, 2}$ has properly simulated Game $_{\kappa, 1}$ in this case.

In summary, $\mathcal{B}_{\kappa, 2}$ has properly simulated either Game $_{\kappa, 1}$ or Game ${ }_{\kappa, 2}$ for $\mathcal{A}$, depending on the distribution of ( $T_{1}, T_{2}, T_{3}, T_{4}$ ). It can therefore leverage $\mathcal{A}$ 's advantage $\epsilon$ between these games to obtain an advantage $\epsilon-6 / q$ against the Subspace assumption in $G_{2}$, namely $\operatorname{Adv}_{\mathcal{B}_{\kappa, 2}}^{\mathrm{DS} 2}(\lambda)=\epsilon-6 / q$.

Lemma 6. For any adversary $\mathcal{A}, \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Final }}}(\lambda) \leq \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\nu, 2}}(\lambda)+1 / q$.

Proof. To prove this lemma, we show the joint distributions of

$$
\left(\mathrm{mpk}, \mathrm{CT}_{e k_{\sigma_{\beta}^{*}}^{(\mathrm{SF})}}^{\left(\mathrm{rcv}_{\beta}^{*}\right.},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game $_{\nu, 2}$ and that of

$$
\left(\mathrm{mpk}, \mathrm{CT}_{e k_{\sigma_{\mathrm{R}}}, \mathrm{rcvR}}^{(\mathrm{R})},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game $_{\text {Final }}$ are equivalent for the adversary's view, where $\mathrm{CT}_{e k_{\sigma_{R}}, r c v_{R}}^{(\mathrm{R})}$ is a semifunctional encryption of a random message in $G_{T}$ and under two random identities in $\mathbb{Z}_{q}$.

For this purpose, we pick $\mathbf{A}:=\left(\xi_{i, j}\right) \stackrel{R}{\leftarrow} \mathbb{Z}_{q}^{4 \times 4}$ and define new dual orthonormal bases $\mathbb{F}:=\left(\mathbf{f}_{1}, \ldots, \mathbf{f}_{8}\right)$, and $\mathbb{F}^{*}:=\left(\mathbf{f}_{1}^{*}, \ldots, \mathbf{f}_{8}^{*}\right)$ as follows:

$$
\left(\begin{array}{c}
\mathbf{f}_{1} \\
\mathbf{f}_{2} \\
\mathbf{f}_{3} \\
\mathbf{f}_{4} \\
\mathbf{f}_{5} \\
\mathbf{f}_{6} \\
\mathbf{f}_{7} \\
\mathbf{f}_{8}
\end{array}\right):\left(\begin{array}{cccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\

\mathbf{d}_{8}^{*}
\end{array}\right) .
$$

It is easy to verify that $\mathbb{F}$ and $\mathbb{F}^{*}$ are also dual orthonormal, and are distributed the same as $\mathbb{D}$ and $\mathbb{D}^{*}$.

Then the master public key, challenge ciphertext, and queried secret keys, (mpk, $\left.\mathrm{CT}_{e k_{\sigma_{\beta}^{*}}^{(\mathrm{SF})}, \mathrm{rcv}_{\beta}^{*}},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)$ in $\mathrm{Game}_{\nu, 2}$ are expressed over bases $\mathbb{D}$ and $\mathbb{D}^{*}$ as

$$
\begin{aligned}
& \mathrm{mpk}:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}\right\}, \quad e k_{\sigma_{\beta}^{*}}:=g_{1}^{\eta \mathbf{d}_{\mathbf{3}}+r\left(\sigma_{\beta}^{*} \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{\mathbf{4}}\right)}, \\
& \mathrm{CT}_{e k_{\sigma_{\beta}^{*}}, \mathrm{rcv}_{\beta}^{*}}^{(\mathrm{SF})}:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\alpha}\right)^{z},\right. \\
& \left.\mathrm{C}_{0}=e k_{\sigma_{\beta}^{*}} \cdot g_{1}^{z\left(\mathbf{d}_{\mathbf{1}}+\mathrm{rcc}\right.}{ }_{\beta}^{*} \mathbf{d}_{\mathbf{2}}\right)+\left[r_{5} \mathbf{d}_{\mathbf{5}}+r_{6} \mathbf{d}_{\mathbf{6}}+r_{7} \mathbf{d}_{\mathbf{7}}+r_{8} \mathbf{d}_{\mathbf{8}}\right] \\
& \left.=g_{1}^{\eta \mathbf{d}_{3}+r\left(\sigma_{\beta}^{*} \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{4}\right)+z\left(\mathbf{d}_{\mathbf{1}}+\operatorname{rcv}_{\beta}^{*} \mathbf{d}_{\mathbf{2}}\right)+\left[r_{5} \mathbf{d}_{\mathbf{5}}+r_{6} \mathbf{d}_{\mathbf{6}}+r_{7} \mathbf{d}_{\mathbf{7}}+r_{8} \mathbf{d}_{\mathbf{8}}\right]}\right\}, \\
& \mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{d}_{1}{ }^{*}+s_{1, \ell}\left(\rho_{\ell} \mathbf{d}_{1}{ }^{*}-\mathbf{d}_{2}{ }^{*}\right)+s_{\ell} \mathbf{d}_{3}{ }^{*}+\left[s_{5,1, \ell} \mathbf{d}_{5}{ }^{*}+s_{6,1, \ell} \mathbf{d}_{6}{ }^{*}+s_{7,1, \ell} \mathbf{d}_{7}{ }^{*}\right]},\right. \\
& k_{2}=g_{2}^{s_{2, \ell}\left(\rho_{\ell} \mathbf{d}_{1}{ }^{*}-\mathbf{d}_{\mathbf{2}}{ }^{*}\right)+s_{\ell} \mathbf{d}_{4}{ }^{*}+\left[s_{5,2, \ell} \mathbf{d}_{5}{ }^{*}+s_{6,2, \ell} \mathbf{d}_{\mathbf{6}}{ }^{*}+s_{8,2, \ell} \mathbf{d}_{\mathbf{8}}{ }^{*}\right],} \\
& \left.k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\}_{\ell \in[\nu]} .
\end{aligned}
$$

Then we can express them over bases $\mathbb{F}$ and $\mathbb{F}^{*}$ as

$$
\begin{aligned}
& \mathrm{mpk}:=\left\{\mathbb{G} ; g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{f}_{1}}, g_{1}^{\mathbf{f}_{2}}\right\}, \quad e k_{\sigma_{\beta}^{*}}:=g_{1}^{\eta \mathbf{d}_{\mathbf{3}}+r\left(\sigma_{\beta}^{*} \mathbf{d}_{3}-\mathbf{d}_{4}\right)}, \\
& \mathrm{CT}_{e k_{\sigma_{\mathrm{R}}}, \mathrm{rcv}}^{(\mathrm{R})}:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\alpha}\right)^{z},\right. \\
& \left.\mathrm{C}_{0}=e k_{\sigma_{\beta}^{*}} \cdot g_{1}^{z\left(\mathbf{d}_{1}+\mathrm{rcv}\right.}{ }_{\beta}^{*} \mathbf{d}_{\mathbf{2}}\right)+\left[r_{5} \mathbf{d}_{\mathbf{5}}+r_{6} \mathbf{d}_{\mathbf{6}}+r_{7} \mathbf{d}_{7}+r_{8} \mathbf{d}_{\mathbf{8}}\right] \\
& \left.=g_{1}^{\eta \mathbf{f}_{3}+\left(r_{3} \mathbf{f}_{3}+r_{4} \mathbf{f}_{4}+r_{1} \mathbf{f}_{1}+r_{2} \mathbf{f}_{2}\right)+\left[r_{5} \mathbf{f}_{5}+r_{6} \mathbf{f}_{6}+r_{7} \mathbf{f}_{7}+r_{8} \mathbf{f}_{8}\right]}\right\}, \\
& \mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}:=\left\{k_{1}=g_{2}^{\alpha \mathbf{f}_{1}{ }^{*}+s_{1, \ell}\left(\rho_{\ell} \mathbf{f}_{1}{ }^{*}-\mathbf{f}_{2}{ }^{*}\right)+s_{\ell} \mathbf{f}_{\mathbf{3}}{ }^{*}+\left[t_{5,1, \ell} \mathbf{f}_{5}{ }^{*}+t_{6,1, \ell} \mathbf{f}_{6}{ }^{*}+t_{7,1, \ell} \mathbf{f}_{7}{ }^{*}+t_{8,1, \ell} \mathbf{f}_{8}{ }^{*}\right]},\right. \\
& k_{2}=g_{2}^{s_{2, \ell}\left(\rho_{\ell} \mathbf{f}_{1}{ }^{*}-\mathbf{f}_{2}{ }^{*}\right)+s_{\ell} \mathbf{f}_{4}{ }^{*}+\left[t_{5,2, \ell} \mathbf{f}_{5}{ }^{*}+t_{6,2, \ell} \mathbf{f}_{6}{ }^{*}+t_{7,2, \ell} \mathbf{f}_{7}{ }^{*}+t_{8,2, \ell} \mathbf{f}_{8}{ }^{*}\right]} \text {, } \\
& \left.k_{3}=\left(g_{T}^{\eta}\right)^{s}\right\}_{\ell \in[\nu]} .
\end{aligned}
$$

where

$$
\begin{aligned}
& r_{1}:=z-r_{5} \xi_{1,1}-r_{6} \xi_{2,1}-r_{7} \xi_{3,1}-r_{8} \xi_{4,1} \\
& r_{2}:=z \cdot \operatorname{rcv}_{\beta}^{*}-r_{5} \xi_{1,2}-r_{6} \xi_{2,2}-r_{7} \xi_{3,2}-r_{8} \xi_{4,2}, \\
& r_{3}:=r \cdot \sigma_{\beta}^{*}-r_{5} \xi_{1,3}-r_{6} \xi_{2,3}-r_{7} \xi_{3,3}-r_{8} \xi_{4,3} \\
& r_{4}:=-r-r_{5} \xi_{1,4}-r_{6} \xi_{2,4}-r_{7} \xi_{3,4}-r_{8} \xi_{4,4} \\
& \left\{\begin{array}{l}
t_{5,1, \ell}:=\alpha \cdot \xi_{1,1}+s_{1, \ell} \rho_{\ell} \cdot \xi_{1,1}-s_{1, \ell} \cdot \xi_{1,2}+s_{\ell} \cdot \xi_{1,3}+s_{5,1, \ell} \\
t_{6,1, \ell}:=\alpha \cdot \xi_{2,1}+s_{1, \ell} \rho_{\ell} \cdot \xi_{2,1}-s_{1, \ell} \cdot \xi_{2,2}+s_{\ell} \cdot \xi_{2,3}+s_{6,1, \ell} \\
t_{7,1, \ell}:=\alpha \cdot \xi_{3,1}+s_{1, \ell} \rho_{\ell} \cdot \xi_{3,1}-s_{1, \ell} \cdot \xi_{3,2}+s_{\ell} \cdot \xi_{3,3}+s_{7,1, \ell} \\
t_{8,1, \ell}:=\alpha \cdot \xi_{4,1}+s_{1, \ell} \rho_{\ell} \cdot \xi_{4,1}-s_{1, \ell} \cdot \xi_{4,2}+s_{\ell} \cdot \xi_{4,3}
\end{array}\right\}_{\ell \in[\nu]} \\
& \left\{\begin{array}{l}
t_{5,2, \ell}:=s_{2, \ell} \rho_{\ell} \cdot \xi_{1,1}-s_{2, \ell} \cdot \xi_{1,2}+s_{\ell} \cdot \xi_{1,4}+s_{5,2, \ell} \\
t_{6,2, \ell}:=s_{2, \ell} \rho_{\ell} \cdot \xi_{2,1}-s_{2, \ell} \cdot \xi_{2,2}+s_{\ell} \cdot \xi_{2,4}+s_{6,2, \ell} \\
t_{7,2, \ell}:=s_{2, \ell} \rho_{\ell} \cdot \xi_{3,1}-s_{2, \ell} \cdot \xi_{3,2}+s_{\ell} \cdot \xi_{3,4} \\
t_{8,2, \ell}:=s_{2, \ell} \rho_{\ell} \cdot \xi_{4,1}-s_{2, \ell} \cdot \xi_{4,2}+s_{\ell} \cdot \xi_{4,4}+s_{8,2, \ell}
\end{array}\right\}_{\ell \in[\nu]}
\end{aligned}
$$

which are all uniformly distributed if $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equation 3 is a nonzero vector, since $\left(z, r,\left\{\xi_{i, j}\right\}_{i \in[4], j \in[4]},\left\{s_{i, j, \ell}\right\}_{i=5, \ldots, 8 ; j=1,2 ; \ell \in[\nu]}\right)$ are all uniformly picked from $\mathbb{Z}_{q}$.

In other words, the coefficients $\left(z, z \cdot r \mathrm{rv}_{\beta}^{*}, r \sigma_{\beta}^{*},-r\right)$ of $\mathbf{d}_{1}, \mathbf{d}_{2}, \mathbf{d}_{3}, \mathbf{d}_{4}$ in the $\mathrm{C}_{0}$ term of the challenge ciphertext is changed to random coefficients $\left(r_{1}, r_{2}, r_{3}, r_{4}\right) \in$ $\mathbb{Z}_{q}^{4}$ of $\mathbf{f}_{1}, \mathbf{f}_{2}, \mathbf{f}_{3}, \mathbf{f}_{4}$, thus the challenge ciphertext can be viewed as a semi-functional encryption of a random message in $G_{T}$ and under two random identities in $\mathbb{Z}_{q}$. Moreover, all coefficients $\left\{t_{i, j, \ell}\right\}_{i=5, \ldots, 8 ; j=1,2 ; \ell \in[\nu]}$ of $\mathbf{f}_{5}^{*}, \mathbf{f}_{6}^{*}, \mathbf{f}_{7}^{*}, \mathbf{f}_{8}^{*}$ in the $\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}$ are all uniformly distributed since $\left\{s_{i, j, \ell}\right\}_{i=5, \ldots, 8 ; j=1,2 ; \ell \in[\nu]}$ of $\mathbf{d}_{5}^{*}, \mathbf{d}_{6}^{*}, \mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ are all independent random values. Thus

$$
\left(\mathrm{mpk}, \mathrm{CT}_{e k_{\sigma_{\beta}^{*}}^{(\mathrm{SF})}}^{\mathrm{rcv}}{ }_{\beta}^{*},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

expressed over bases $\mathbb{F}$ and $\mathbb{F}^{*}$ is properly distributed as

$$
\left(\mathrm{mpk}, \mathrm{CT}_{e k_{\sigma_{R}}, \mathrm{rcv}_{R}}^{(\mathrm{R})},\left\{\mathrm{dk}_{\rho_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game Final .
In the adversary's view, both $\left(\mathbb{D}, \mathbb{D}^{*}\right)$ and $\left(\mathbb{F}, \mathbb{F}^{*}\right)$ are consistent with the same master public key. Therefore, the challenge ciphertext and queried secret keys above can be expressed as keys and ciphertext in two ways, in Game ${ }_{\nu, 2}$ over bases $\left(\mathbb{D}, \mathbb{D}^{*}\right)$ and in $G^{\text {Game }}{ }_{\text {Final }}$ over bases $\left(\mathbb{F}, \mathbb{F}^{*}\right)$. Thus, $\mathrm{Game}_{\nu, 2}$ and Game ${ }_{\text {Final }}$ are statistically indistinguishable except with probability $1 / q$ (namely, the case $\left(r_{5}, r_{6}, r_{7}, r_{8}\right)$ defined in Equation 3 is the zero vector).

Lemma 7. For any adversary $\mathcal{A}, \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Final }}}(\lambda)=0$.

Proof. The value of $\beta$ is independent from the adversary's view in Game ${ }_{\text {Final }}$. Hence, $\operatorname{Adv}_{\mathcal{A}}^{\text {Game }_{\text {Final }}}(\lambda)=0$.

In Game $_{\text {Final }}$, the challenge ciphertext is a semi-functional encryption of a random message in $G_{T}$ and under two random identities in $\mathbb{Z}_{q}$, independent of the two messages and the challenge identities provided by $\mathcal{A}$. Thus, our IBME scheme satisfies the privacy property defined in Def. 8 under the SXDH assumption.

Theorem 2. The proposed IB-ME scheme satisfies authenticity under the Symmetric External Diffie-Hellman assumption. More precisely, for any PPT adversary $\mathcal{A}$ break the authenticity of our IB-ME scheme, its advantage $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\mathrm{ib}}-\text { auth }}(\lambda)$ is negligible.

Proof. The authenticity property intuitively says that if an adversary does not hold the corresponding encryption key $e k_{\sigma}$ produced by the challenger, it cannot compute a valid ciphertext under the identity $\sigma$. Thus, it is corresponding to the unforgeability of signature, and we can directly reduce the authenticity to the security of the IBE system.

Assume that there is a PPT adversary $\mathcal{A}$ which breaks the authenticity property with advantage $\epsilon$, we then employ it to build another PPT algorithm $\mathcal{B}$ to break a fully secure IBE system which consists of the following algorithms:

- IBE.Setup $\left(1^{\lambda}\right)$ : The same as the Setup algorithm, except that the master public key is $m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}$, and the master secret key is $m s k:=\left\{\eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}\right\}$.
- IBE.KeyGen $(m s k, \sigma)$ : The same as the SKGen algorithm, and the secret key is $s k_{\sigma}:=g_{1}^{\eta \mathbf{d}_{3}+r\left(\sigma \mathbf{d}_{3}-\mathbf{d}_{4}\right)}$.
- IBE.Enc $(m p k, \sigma, m)$ : Similar to the RKGen algorithm, and the ciphertext is $c t:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\eta}\right)^{s}, \mathrm{C}_{0}=g_{2}^{s\left(\mathbf{d}_{3}^{*}+\sigma \mathbf{d}_{4}^{*}\right)}\right\}$.
- IBE.Dec $\left(m p k, s k_{\sigma}, c t\right):$ Compute the message as $m:=\mathrm{C} / e\left(\mathrm{C}_{0}, s k_{\sigma}\right)$.

Oracles $\mathrm{O}_{1}, \mathrm{O}_{2}$ are implemented by SKGen(mpk, msk, $\cdot$ ) and RKGen(mpk, msk, $\cdot$ ) and are simulated by $\mathcal{B}$ as follows:

1. SKGen(mpk, msk, $\cdot): \mathcal{A}$ launches a query for identity $\sigma$ to $\mathrm{O}_{1}$, then $\mathcal{B}$ transfers this identity $\sigma$ to the IBE system for generating secret key. It uses the IBE.KeyGen algorithm's output to answer this query and returns the secret key $s k_{\sigma}$ to $\mathcal{B}$. Finally, $\mathcal{B}$ uses this secret key $s k_{\sigma}$ from IBE as $e k_{\sigma}$ to answer $\mathcal{A}$ 's query for the encryption key.
2. RKGen(mpk, msk, $\cdot$ ): $\mathcal{A}$ launches a query for identity $\rho$ to $\mathrm{O}_{2}$, then $\mathcal{B}$ transfers this identity $\rho$ to the IBE system. It uses $m p k$ (in IBE) to generate the corresponding keys, randomly picks $s, s_{1}, s_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$, computes

$$
k_{1}=g_{2}^{\alpha \mathbf{d}_{1}^{*}+s_{1}\left(\rho \mathbf{d}_{\mathbf{1}}^{*}-\mathbf{d}_{\mathbf{2}}^{*}\right)+s \mathbf{d}_{\mathbf{3}}^{*}}, k_{2}=g_{2}^{s_{2}\left(\rho \mathbf{d}_{\mathbf{1}}^{*}-\mathbf{d}_{\mathbf{2}}^{*}\right)+s \mathbf{d}_{\mathbf{4}}^{*}}, k_{3}=\left(g_{T}^{\eta}\right)^{s},
$$

and returns these keys to $\mathcal{B}$. Finally, $\mathcal{B}$ uses $d k_{\rho}=\left\{k_{1}, k_{2}, k_{3}\right\}$ to answer $\mathcal{A}$ 's query for the decryption key.

Suoopse that $\operatorname{Adv}_{\mathcal{A}} \operatorname{Game}_{\mathrm{ib}}{ }^{\text {-auth }}(\lambda)=\epsilon$, where $\epsilon$ is a non-negligible value. Then we can build an algorithm $\mathcal{B}$ whose $\operatorname{Adv}_{\mathcal{B}}{ }^{\mathrm{IBE}}(\lambda)=\epsilon$ as follow:

Upon $\mathcal{A}$ making a query of $(\sigma, \rho), \mathcal{B}$ generates the encryption key and decryption key to answer this query by simulating $\mathrm{O}_{1}, \mathrm{O}_{2}$, and sends ( $e k_{\sigma}, d k_{\rho}$ ) back to $\mathcal{A}$. Then $\mathcal{A}$ can find another $\sigma^{*} \neq$ snd with $\epsilon$ probability such that $\sigma^{*}$ is also valid for decryption of $c t$, and sends $\sigma^{*}$ to $\mathcal{B}$. Note that the fact snd and $\sigma^{*}$ are both valid for $c t_{\sigma, \text { rcv }}$ implies for a ciphertext associated with $\sigma$ in the underlying IBE, there would be two different secret keys associated with snd and $\sigma^{*}$ respectively. The $s k_{\sigma^{*}}$ in IBE is identical to the $e k_{\sigma^{*}}$ in IB-ME. Therefore, $\mathcal{B}$ can make secret key query for snd, and challenge $\left(m_{0}, \sigma_{0}\right)$ and $\left(m_{1}, \sigma^{*}\right)$. Then $\mathcal{B}$ can distinguish the challenge ciphertext easily by using the secret key associated with $\sigma^{*}$ and break this IBE system.

This means that by this simulation, we have successfully reduced the authenticity of IB-ME to the security of this IBE system. And we have

$$
\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\mathrm{ib} \text {-auth }}}(\lambda) \leq \operatorname{Adv}_{\mathcal{B}}^{\mathrm{IBE}}(\lambda)
$$

That is to say, if an adversary cannot successfully break the IBE system we constructed, it cannot forge a valid ciphertext in our IB-ME scheme either. See Appendix A, where we show that this IBE system is fully secure, i.e., the advantage of $\mathcal{B}$ winning the IBE game defined in Def. 5 is negligible. Thus for any PPT adversary $\mathcal{A}$, its advantage of breaking the authenticity property of our IB-ME scheme is negligible.

Note that we have challenged $m$ and $\sigma$ at the same time, but in fact, we do not need to challenge identity $\sigma$ at all. That is to say the security of a trivial IBE is sufficient and anonymity is not required. Because another $\sigma^{*} \neq$ snd can be obtained from $\mathcal{A}$ during the proof, and $\mathcal{B}$ sends identity snd and ( $m_{0}, m_{1}$ ) to the challenger, the same result can be obtained.

## 5 Conclusion

In this paper, we propose the first identity-based matchmaking encryption scheme under the standard assumptions in the standard model. We construct our IB-ME scheme by a variant of two-level anonymous IBE, which is based on Okamoto and Takashima's dual pairing vector spaces, and its security reductions rely on Waters's dual system encryption under the SXDH assumption. Our directly constructed scheme does not rely on other cryptographic tools such as noninteractive zero-knowledge proof systems. Meanwhile, we leave several questions. First, although all parameters in our scheme have constant numbers of group elements, the size should be shorter and the number of pairing for decryption should be reduced to improve efficiency. Second, construct IB-ME schemes that satisfy the enhanced privacy [15] under standard assumptions. Third, practical extensions such as revocability and traceability are further works.

## A Security Proof of the constructed IBE scheme

We define the IBE scheme built from Construction 4.1 and prove its security. This IBE scheme consisted of the following algorithms:

- Setup $\left(1^{\lambda}\right) \rightarrow(m p k, m s k)$ : This algorithm takes in the security parameter $1^{\lambda}$ and generates a bilinear pairing $\mathbb{G}:=\left(q, G_{1}, G_{2}, G_{T}, g_{1}, g_{2}, e\right)$ for sufficiently large prime order $q$. The algorithm samples random dual orthonormal bases $\left(\mathbb{D}, \mathbb{D}^{*}\right) \stackrel{R}{\leftarrow} \operatorname{Dual}\left(\mathbb{Z}_{\mathrm{q}}^{8}\right)$. Let $\mathbf{d}_{\mathbf{1}}, \ldots, \mathbf{d}_{\mathbf{8}}$ denote the elements of $\mathbb{D}$ and $\mathbf{d}_{\mathbf{1}}^{*}, \ldots, \mathbf{d}_{\mathbf{8}}^{*}$ denote the elements of $\mathbb{D}^{*}$. Let $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{\mathbf{1}}^{*}}$. It also picks $\alpha, \eta \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and outputs the master public key as

$$
m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}
$$

and the master secret key

$$
m s k:=\left\{\eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}\right\}
$$

- KeyGen $(m p k, m s k, \sigma) \rightarrow s k_{\sigma}$ : This algorithm picks $r \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$. The secret key is computed as

$$
s k_{\sigma}:=g_{1}^{\eta \mathbf{d}_{3}+r\left(\sigma \mathbf{d}_{\mathbf{3}}-\mathbf{d}_{\mathbf{4}}\right)} .
$$

$-\operatorname{Enc}(m p k, \sigma, m) \rightarrow c t$ : This algorithm picks $s \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and a random identity $\rho$, and forms the ciphertext as

$$
c t:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\eta}\right)^{s}, \mathrm{C}_{0}=g_{2}^{s\left(\mathbf{d}_{3}^{*}+\sigma \mathbf{d}_{4}^{*}\right)}\right\} .
$$

- $\operatorname{Dec}\left(m p k, s k_{\sigma}, c t\right) \rightarrow m$ : This algorithm computes the message as

$$
m:=\frac{\mathrm{C}}{e\left(\mathrm{C}_{0}, s k_{\sigma}\right)}
$$

Theorem 3. This IBE scheme is fully secure under the Symmetric External Diffie-Hellman assumption. More precisely, for any adversary $\mathcal{A}$ against the IBE scheme, there exist probabilistic algorithms $\mathcal{B}_{0}, \mathcal{B}_{1}, \ldots, \mathcal{B}_{\nu}$ whose running times are essentially the same as that of $\mathcal{A}$, such that

$$
\operatorname{Adv}_{\mathcal{A}}^{\mathrm{IBE}}(\lambda) \leq \operatorname{Adv}_{\mathcal{B}_{0}}^{\mathrm{DDH} 2}(\lambda)+\sum_{\kappa=1}^{\nu} \operatorname{Adv}_{\mathcal{B}_{\kappa}}^{\mathrm{DDH} 1}(\lambda)+(6 \nu+3) / q
$$

where $\nu$ is the maximum number of $\mathcal{A}$ 's key queries.
We adopt the dual system encryption methodology by Waters [31] to prove the security of this IBE scheme. Note that we only need to consider the vector bases $\mathbf{d}_{\mathbf{3}}, \mathbf{d}_{\mathbf{4}}$ and ignore the bases $\mathbf{d}_{\mathbf{1}}, \mathbf{d}_{\mathbf{2}}$. We first give the corresponding algorithms for the generation of semi-functional keys and semi-functional ciphertext.

KeyGenSF: The algorithm picks $r, r_{7}, r_{8} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms a semi-functional secret key as

$$
\begin{equation*}
\mathrm{SK}_{\sigma}^{(\mathrm{SF})}:=g_{1}^{\eta \mathbf{d}_{3}+r\left(\sigma \mathbf{d}_{3}-\mathbf{d}_{4}\right)+\left[r_{7} \mathbf{d}_{7}+r_{8} \mathbf{d}_{8}\right]} \tag{8}
\end{equation*}
$$

EncryptSF: The algorithm picks $s, s_{7}, s_{8} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and forms a semi-functional ciphertext as

$$
\begin{equation*}
\mathrm{CT}_{\sigma}^{(\mathrm{SF})}=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\eta}\right)^{s}, \mathrm{C}_{0}=g_{2}^{s\left(\mathbf{d}_{\mathbf{3}}^{*}+\sigma \mathbf{d}_{\mathbf{4}}^{*}\right)+\left[s_{7} \mathbf{d}_{\mathbf{7}}^{*}+s_{8} \mathbf{d}_{\mathbf{8}}^{*}\right]}\right\} \tag{9}
\end{equation*}
$$

Hereafter we will ignore $C$ since it is always correctly generated. We observe that if one applies the decryption procedure with a semi-functional key and a normal ciphertext, decryption will succeed because $\mathbf{d}_{\mathbf{7}}, \mathbf{d}_{\mathbf{8}}$ are orthogonal to all of the vectors in exponent of $\mathrm{C}_{0}$, and hence have no effect on decryption. Similarly, decryption of a semi-functional ciphertext by a normal key will also succeed because $\mathbf{d}_{\mathbf{7}}^{*}, \mathbf{d}_{\mathbf{8}}^{*}$ are orthogonal to all of the vectors in the exponent of the key. When both the ciphertext and key are semi-functional, the result of $e\left(\mathrm{C}_{0}, \mathrm{SK}_{\sigma}\right)$ will have an additional term, namely

$$
e\left(g_{1}, g_{2}\right)^{r_{7} s_{7} \mathbf{d}_{\mathbf{7}} \cdot \mathbf{d}_{7}^{*}+r_{8} s_{8} \mathbf{d}_{\mathbf{8}} \cdot \mathbf{d}_{\mathbf{8}}^{*}}=g_{T}^{\left(r_{7} s_{7}+r_{8} s_{8}\right)} .
$$

Decryption will then fail unless $r_{7} s_{7}+r_{8} s_{8} \equiv 0(\bmod q)$. If this modular equation holds, we say that the key and ciphertext pair is nominally semi-functional.

For a probabilistic polynomial-time adversary $\mathcal{A}$ which makes $\nu$ key queries $\sigma_{1}, \ldots, \sigma_{\nu}$, our proof of security consists of the following sequence of games between $\mathcal{A}$ and a challenger $\mathcal{B}$.

- Game ${ }_{\text {Real }}$ : is the real security game.
- Game 0 : is the same as Game $_{\text {Real }}$ except that the challenge ciphertext is semifunctional.
$-\mathrm{Game}_{\kappa}$ : for $\kappa$ from 1 to $\nu, \mathrm{Game}_{\kappa}$ is the same as $\mathrm{Game}_{0}$ except that the first $\kappa$ keys are semi-functional and the remaining keys are normal.
- Game ${ }_{\text {Final }}$ : is the same as $\mathrm{Game}_{\nu}$, except that the challenge ciphertext is a semi-functional encryption of a random message in $G_{T}$ and under a random identity in $\mathbb{Z}_{q}$. We denote the challenge ciphertext in Game Final as $\mathrm{CT}_{\sigma_{\mathrm{R}}}^{(\mathrm{R})}$.

We prove following lemmas to show the above games are indistinguishable by following an analogous strategy of $[12,18,19]$. We let $\operatorname{Adv}_{\mathcal{A}}$ Game $_{\text {Real }}$ denote an adversary $\mathcal{A}$ 's advantage in the real game.

Lemma 8. Suppose that there exists an adversary $\mathcal{A}$ where $\mid \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Real }}}(\lambda)-$ $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{0}}(\lambda) \mid=\epsilon$. Then there exists an algorithm $\mathcal{B}_{0}$ such that $\operatorname{Adv}_{\mathcal{B}_{0}}^{\mathrm{DS} 2}(\lambda)=$ $\epsilon-2 / q$, with $K=4$ and $N=8$.

Proof. $\mathcal{B}_{0}$ is given

$$
D:=\left(\mathbb{G} ; g_{1}^{\mathbf{b}_{1}}, g_{1}^{\mathbf{b}_{2}}, g_{1}^{\mathbf{b}_{3}}, g_{1}^{\mathbf{b}_{4}}, g_{2}^{\mathbf{b}_{1}^{*}}, \ldots, g_{2}^{\mathbf{b}_{8}^{*}}, U_{1}, U_{2}, U_{3}, U_{4}, \mu_{2}\right)
$$

along with $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. And in $D$ we have that $U_{1}=g_{1}^{\mu_{1} \mathbf{b}_{1}+\mu_{2} \mathbf{b}_{5}}, U_{2}=$ $g_{1}^{\mu_{1} \mathbf{b}_{\mathbf{2}}+\mu_{2} \mathbf{b}_{\mathbf{6}}}, U_{3}=g_{1}^{\mu_{1} \mathbf{b}_{\mathbf{3}}+\mu_{2} \mathbf{b}_{\mathbf{7}}}, U_{4}=g_{1}^{\mu_{1} \mathbf{b}_{\mathbf{4}}+\mu_{2} \mathbf{b}_{\mathbf{8}}}$. We require that $\mathcal{B}_{0}$ decides whether $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are distributed as
$\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right) \quad$ or $\quad\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$.
$\mathcal{B}_{0}$ simulates $G^{2}$ Real $_{\text {Real }}$ or $\mathrm{Game}_{0}$ with $\mathcal{A}$ depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. To compute the master public key and master secret key, $\mathcal{B}_{0}$ chooses a random invertible matrix $\mathbf{A} \in \mathbb{Z}_{q}^{4 \times 4}$. We then implicitly set dual orthonormal bases $\mathbb{D}, \mathbb{D}^{*}$ to:

$$
\begin{aligned}
& \mathbf{d}_{1}:=\mathbf{b}_{1}, \ldots, \mathbf{d}_{4}:=\mathbf{b}_{4}, \quad\left(\mathbf{d}_{5}, \ldots, \mathbf{d}_{8}\right):=\left(\mathbf{b}_{5}, \ldots, \mathbf{b}_{8}\right) \mathbf{A} \\
& \mathbf{d}_{1}^{*}:=\mathbf{b}_{1}^{*}, \ldots, \mathbf{d}_{4}^{*}:=\mathbf{b}_{4}^{*}, \quad\left(\mathbf{d}_{5}^{*}, \ldots, \mathbf{d}_{8}^{*}\right):=\left(\mathbf{b}_{5}^{*}, \ldots, \mathbf{b}_{8}^{*}\right)\left(\mathbf{A}^{-1}\right)^{\top} .
\end{aligned}
$$

We note that $\mathbb{D}, \mathbb{D}^{*}$ are properly distributed, and reveal no information about A. Moreover, $\mathcal{B}_{0}$ cannot generate $g_{1}^{\mathbf{d}_{5}}, g_{1}^{\mathbf{d}_{6}}, g_{1}^{\mathbf{d}_{7}}, g_{1}^{\mathbf{d}_{8}}$, but these will not be needed for creating normal keys. $\mathcal{B}_{0}$ chooses random value $\alpha, \eta \in \mathbb{Z}_{q}$ and computes $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{1}^{*}}$. It then gives $\mathcal{A}$ the master public key

$$
m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{\mathbf{4}}^{*}}\right\}
$$

The master secret key

$$
m s k:=\left\{\eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}\right\} .
$$

is known to $\mathcal{B}_{0}$, which allows $\mathcal{B}_{0}$ to respond to all of $\mathcal{A}$ 's key queries by calling the normal key generation algorithm.
$\mathcal{A}$ sends $\mathcal{B}_{0}$ two pairs $\left(m_{0}, \sigma_{0}^{*}\right)$ and $\left(m_{1}, \sigma_{1}^{*}\right)$. $\mathcal{B}_{0}$ chooses a random bit $\beta \in$ $\{0,1\}$ and picks $s_{1}, s_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$, and then encrypts $m_{\beta}$ under $\sigma_{\beta}^{*}$ as follows:

$$
\mathrm{C}=m_{\beta} \cdot\left(e\left(g_{1}^{\mathbf{b}_{1}}, T_{1}\right)\right)^{\eta}=m_{\beta} \cdot\left(g_{T}^{\eta}\right)^{s}, \quad \mathrm{C}_{0}=T_{3} \cdot T_{4}^{\sigma_{\beta}^{*}},
$$

where $\mathcal{B}_{0}$ has implicitly set $s:=\tau_{1}$. It gives the ciphertext $c t=\left(\mathrm{C}, \mathrm{C}_{0}\right)$ to $\mathcal{A}$.
Now, if ( $T_{1}, T_{2}, T_{3}, T_{4}$ ) are equal to $\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}}\right)$, then this is a properly distributed normal encryption of $m_{\beta}$. In this case, $\mathcal{B}_{0}$ has properly simulated Game ${ }_{\text {Real }}$. If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{2}^{\tau_{1} \mathbf{b}_{1}^{*}+\tau_{2} \mathbf{b}_{5}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{2}^{*}+\tau_{2} \mathbf{b}_{6}^{*}}, g_{2}^{\tau_{1} \mathbf{b}_{3}^{*}+\tau_{2} \mathbf{b}_{7}^{*}}\right.$, $\left.g_{2}^{\tau_{1} \mathbf{b}_{4}^{*}+\tau_{2} \mathbf{b}_{8}^{*}}\right)$ instead, then the ciphertext element $\mathrm{C}_{0}$ has an additional term of

$$
\tau_{2} \mathbf{b}_{\mathbf{7}}^{*}+\tau_{2} \sigma_{\beta}^{*} \mathbf{b}_{\mathbf{8}}^{*}
$$

in its exponent. The coefficients here in the basis $\mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$ form the vector $\tau_{2}\left(1, \sigma_{\beta}^{*}\right)$. To compute the coefficients in the basis $\mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$, we use the change of basis matrix $\mathbf{A}$ and obtain the new vector $\tau_{2} \mathbf{A}^{\top}\left(1, \sigma_{\beta}^{*}\right)^{\top}$. Since $\mathbf{A}$ is random (everything else given to $\mathcal{A}$ has been distributed independently of $\mathbf{A}$, these coefficients are uniformly random except with probability $2 / q$ (namely, the cases $\tau_{2}$ defined in Subspace problem is zero, $\left(s_{7}, s_{8}\right)$ defined in Equation 9 is the zero vector) from Lemma 2. Therefore in this case, $\mathcal{B}_{0}$ has properly simulated $\mathrm{Game}_{0}$. This allows $\mathcal{B}_{0}$ to leverage $\mathcal{A}$ 's advantage $\epsilon$ between Game ${ }_{\text {Real }}$ and Game $_{0}$ to achieve an advantage $\epsilon-\frac{2}{q}$ against the Subspace assumption in $G_{2}$, namely $\operatorname{Adv}_{\mathcal{B}_{0}}^{\text {DS2 }}(\lambda)=\epsilon-\frac{2}{q}$.

Lemma 9. Suppose that there exists an adversary $\mathcal{A}$ where $\mid \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\kappa-1}}(\lambda)-$ $\operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\kappa}}(\lambda) \mid=\epsilon$. Then there exists an algorithm $\mathcal{B}_{\kappa}$ such that $\operatorname{Adv}_{\mathcal{B}_{\kappa}}^{\mathrm{DS} 1}(\lambda)=$ $\epsilon-6 / q$, with $K=4$ and $N=8$.

Proof. $\mathcal{B}_{\kappa}$ is given

$$
D:=\left(\mathbb{G} ; g_{2}^{\mathbf{b}_{1}^{*}}, g_{2}^{\mathbf{b}_{2}^{*}}, g_{2}^{\mathbf{b}_{3}^{*}}, g_{2}^{\mathbf{b}_{4}^{*}}, g_{1}^{\mathbf{b}_{1}}, \ldots, g_{1}^{\mathbf{b}_{8}}, U_{1}, U_{2}, U_{3}, U_{4}, \mu_{2}\right)
$$

along with $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. And in $D$ we have that $U_{1}=g_{2}^{\mu_{1} \mathbf{b}_{1}^{*}+\mu_{2} \mathbf{b}_{5}^{*}}, U_{2}=$ $g_{2}^{\mu_{1} \mathbf{b}_{2}^{*}+\mu_{2} \mathbf{b}_{\mathbf{6}}^{*}}, U_{3}=g_{2}^{\mu_{1} \mathbf{b}_{3}^{*}+\mu_{2} \mathbf{b}_{7}^{*}}, U_{4}=g_{2}^{\mu_{1} \mathbf{b}_{4}^{*}+\mu_{2} \mathbf{b}_{8}^{*}}$. We require that $\mathcal{B}_{\kappa}$ decides whether $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are distributed as
$\left(g_{1}^{\tau_{1} \mathbf{b}_{1}}, g_{1}^{\tau_{1} \mathbf{b}_{2}}, g_{1}^{\tau_{1} \mathbf{b}_{3}}, g_{1}^{\tau_{1} \mathbf{b}_{4}}\right) \quad$ or $\quad\left(g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{5}}, g_{1}^{\tau_{1} \mathbf{b}_{2}+\tau_{2} \mathbf{b}_{6}}, g_{1}^{\tau_{1} \mathbf{b}_{3}+\tau_{2} \mathbf{b}_{7}}, g_{1}^{\tau_{1} \mathbf{b}_{4}+\tau_{2} \mathbf{b}_{8}}\right)$.
$\mathcal{B}_{\kappa}$ simulates Game $_{\kappa}$ or Game ${ }_{\kappa-1}$ with $\mathcal{A}$, depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. To compute the public parameters and master secret key, $\mathcal{B}_{\kappa}$ chooses a random invertible matrix $\mathbf{A} \in \mathbb{Z}_{q}^{4 \times 4}$. We then implicitly set dual orthonormal bases $\mathbb{D}, \mathbb{D}^{*}$ to:

$$
\begin{aligned}
& \mathbf{d}_{1}:=\mathbf{b}_{1}, \ldots, \mathbf{d}_{4}:=\mathbf{b}_{4}, \quad\left(\mathbf{d}_{5}, \ldots, \mathbf{d}_{8}\right):=\left(\mathbf{b}_{5}, \ldots, \mathbf{b}_{8}\right) \mathbf{A} \\
& \mathbf{d}_{1}^{*}:=\mathbf{b}_{1}^{*}, \ldots, \mathbf{d}_{4}^{*}:=\mathbf{b}_{4}^{*}, \quad\left(\mathbf{d}_{5}^{*}, \ldots, \mathbf{d}_{8}^{*}\right):=\left(\mathbf{b}_{5}^{*}, \ldots, \mathbf{b}_{8}^{*}\right)\left(\mathbf{A}^{-1}\right)^{\top} .
\end{aligned}
$$

We note that $\mathbb{D}, \mathbb{D}^{*}$ are properly distributed, and reveal no information about A. $\mathcal{B}_{\kappa}$ chooses random value $\alpha, \eta \in \mathbb{Z}_{q}$ and computes $g_{T}:=e\left(g_{1}, g_{2}\right)^{\mathbf{d}_{1} \cdot \mathbf{d}_{1}^{*}}$. It then gives $\mathcal{A}$ the master public key

$$
m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}, g_{2}^{\mathbf{d}_{1}^{*}}, g_{2}^{\mathbf{d}_{2}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}
$$

The master secret key

$$
m s k:=\left\{\eta, g_{1}^{\mathbf{d}_{3}}, g_{1}^{\mathbf{d}_{4}}\right\}
$$

is known to $\mathcal{B}_{\kappa}$, which allows $\mathcal{B}_{\kappa}$ to respond to all of $\mathcal{A}$ 's key queries by calling the normal key generation algorithm. Since $\mathcal{B}_{\kappa}$ also knows $g_{1}^{\mathbf{d}_{5}}, g_{1}^{\mathbf{d}_{6}}, g_{1}^{\mathbf{d}_{7}}, g_{1}^{\mathbf{d}_{8}}$, it can easily produce semi-functional keys. To answer the first $\kappa$ - 1 key queries that $\mathcal{A}$ makes, $\mathcal{B}_{\kappa}$ runs the semi-functional key generation algorithm to produce semifunctional keys and gives these to $\mathcal{A}$. To answer the $\kappa$-th key query for $\sigma_{\kappa}, \mathcal{B}_{\kappa}$ responds with:

$$
s k_{\sigma_{\kappa}}:=\left(g_{1}^{\mathbf{b}_{3}}\right)^{\eta} \cdot T_{3}^{\sigma_{\kappa}} \cdot T_{4}^{-1} .
$$

This implicitly sets $r:=\tau_{1}$. If $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$ are equal to $\left(g_{1}^{\tau_{1} \mathbf{b}_{1}}, g_{1}^{\tau_{1} \mathbf{b}_{2}}, g_{1}^{\tau_{1} \mathbf{b}_{3}}, g_{1}^{\tau_{1} \mathbf{b}_{4}}\right)$, then this is a properly distributed normal key. If ( $T_{1}, T_{2}, T_{3}, T_{4}$ ) are equal to $\left(g_{1}^{\tau_{1} \mathbf{b}_{1}+\tau_{2} \mathbf{b}_{5}}, g_{1}^{\tau_{1} \mathbf{b}_{2}+\tau_{2} \mathbf{b}_{6}}, g_{1}^{\tau_{1} \mathbf{b}_{3}+\tau_{2} \mathbf{b}_{7}}, g_{1}^{\tau_{1} \mathbf{b}_{4}+\tau_{2} \mathbf{b}_{8}}\right)$, then this is a semi-functional key, whose exponent vector includes

$$
\begin{equation*}
\tau_{2}\left(\sigma_{\kappa} \mathbf{b}_{\mathbf{7}}-\mathbf{b}_{\mathbf{8}}\right) \tag{10}
\end{equation*}
$$

as its component in the span of $\mathbf{b}_{7}, \mathbf{b}_{8}$. To respond to the remaining key queries, $\mathcal{B}_{\kappa}$ simply runs the normal key generation algorithm.

At some point, $\mathcal{A}$ sends $\mathcal{B}_{\kappa}$ two pairs $\left(m_{0}, \sigma_{0}^{*}\right)$ and $\left(m_{1}, \sigma_{1}^{*}\right)$. $\mathcal{B}_{\kappa}$ chooses a random bit $\beta \in\{0,1\}$ and picks $s_{1}, s_{2} \stackrel{R}{\leftarrow} \mathbb{Z}_{q}$ and then encrypts $m_{\beta}$ under $\sigma_{\beta}^{*}$ as follows:

$$
\mathrm{C}=m_{\beta} \cdot\left(e\left(g_{1}^{\mathbf{b}_{1}}, U_{1}\right)\right)^{\eta}=m_{\beta} \cdot\left(g_{T}^{\eta}\right)^{s}, \quad \mathrm{C}_{0}=U_{3} \cdot U_{4}^{\sigma_{\beta}^{*}}
$$

where $\mathcal{B}_{\kappa}$ has implicitly set $s:=\mu_{1}$. The "semi-functional part" of the exponent vector here is:

$$
\begin{equation*}
\mu_{2}\left(\mathbf{b}_{\mathbf{7}}^{*}+\sigma_{\beta}^{*} \mathbf{b}_{\mathbf{8}}^{*}\right) \tag{11}
\end{equation*}
$$

We observe that if $\sigma_{\beta}^{*}=\sigma_{\kappa}$ (which is not allowed), then vectors in Equations 10 and 11 would be orthogonal, resulting in a nominally semi-functional ciphertext and key pair. It gives the ciphertext $\left(\mathrm{C}, \mathrm{C}_{0}\right)$ to $\mathcal{A}$.

We now argue that since $\sigma_{\beta}^{*} \neq \sigma_{\kappa}$, in $\mathcal{A}$ 's view the vectors in Equations 10 and 11 are distributed as random vectors in the spans of $\mathbf{d}_{7}, \mathbf{d}_{8}$ and $\mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$ respectively. To see this, we take the coefficients of vectors in Equations 10 and 11 in terms of the bases $\mathbf{b}_{7}, \mathbf{b}_{8}$ and $\mathbf{b}_{7}^{*}, \mathbf{b}_{8}^{*}$ respectively and translate them into coefficients in terms of the bases $\mathbf{d}_{7}, \mathbf{d}_{8}$ and $\mathbf{d}_{7}^{*}, \mathbf{d}_{8}^{*}$. Using the change of basis matrix $\mathbf{A}$, we obtain the new coefficients (in vector form) as:

$$
\tau_{2} \mathbf{A}^{\top}\left(\sigma_{\kappa},-1\right)^{\top}, \quad \mu_{2} \mathbf{A}^{-1}\left(1, \sigma_{\beta}^{*}\right)^{\top}
$$

Since the distribution of everything given to $\mathcal{A}$ except for the $\kappa$-th key and the challenge ciphertext is independent of the random matrix $\mathbf{A}$ and $\sigma_{\beta}^{*} \neq \sigma_{\kappa}$, we can conclude that these coefficients are uniformly except with probability $4 / q$ (namely, the cases $\mu_{2}$ or $\tau_{2}$ defined in Subspace problem is zero, $\left(r_{7}, r_{8}\right)$ or $\left(s_{7}, s_{8}\right)$ defined in Equations 8 and 9 is the zero vector) from Lemma 2. Thus, $\mathcal{B}_{\kappa}$ has properly simulated Game ${ }_{\kappa}$ in this case.

If ( $T_{1}, T_{2}, T_{3}, T_{4}$ ) are equal to ( $\left.g_{1}^{\tau_{1} \mathbf{b}_{1}}, g_{1}^{\tau_{1} \mathbf{b}_{2}}, g_{1}^{\tau_{1} \mathbf{b}_{3}}, g_{1}^{\tau_{1} \mathbf{b}_{4}}\right)$, then the coefficients of the vector in Equation 11 are uniformly except with probability $2 / q$ (namely, the cases $\mu_{2}$ defined in Subspace problem is zero, $\left(s_{7}, s_{8}\right)$ defined in Equation 9 is the zero vector) from Lemma 2 . Thus, $\mathcal{B}_{\kappa}$ has properly simulated Game ${ }_{\kappa}$ in this case.

In summary, $\mathcal{B}_{\kappa}$ has properly simulated either Game ${ }_{\kappa-1}$ or Game ${ }_{\kappa}$ for $\mathcal{A}$, depending on the distribution of $\left(T_{1}, T_{2}, T_{3}, T_{4}\right)$. It can therefore leverage $\mathcal{A}$ 's advantage $\epsilon$ between these games to obtain an advantage $\epsilon-6 / q$ against the Subspace assumption in $G_{1}$, namely $\operatorname{Adv}_{\mathcal{B}_{\kappa}}^{\mathrm{DS1}^{\mathrm{D}}}(\lambda)=\epsilon-6 / q$.

Lemma 10. For any adversary $\mathcal{A}, \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Final }}}(\lambda) \leq \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\nu}}(\lambda)+1 / q$.
Proof. To prove this lemma, we show the joint distributions of

$$
\left(\mathrm{mpk}, \mathrm{CT}_{\sigma_{\beta}^{*}}^{(\mathrm{SF})},\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game $_{\nu}$ and that of

$$
\left(\mathrm{mpk}, \mathrm{CT}_{\sigma_{\mathrm{R}}}^{(\mathrm{R})},\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game $_{\text {Final }}$ are equivalent for the adversary's view, where $\mathrm{CT}_{\sigma_{\mathrm{R}}}^{(\mathrm{R})}$ is a semifunctional encryption of a random message in $G_{T}$ and under a random identity in $\mathbb{Z}_{q}^{n}$.

For this purpose, we pick $\mathbf{A}:=\left(\xi_{i, j}\right) \leftarrow_{R} \mathbb{Z}_{q}^{2 \times 2}$ and define new dual orthonormal bases $\mathbb{F}:=\left(\mathbf{f}_{1}, \ldots, \mathbf{f}_{8}\right)$, and $\mathbb{F}^{*}:=\left(\mathbf{f}_{1}^{*}, \ldots, \mathbf{f}_{8}^{*}\right)$ as follows:

$$
\begin{aligned}
&\left(\begin{array}{l}
\mathbf{f}_{1} \\
\mathbf{f}_{2} \\
\mathbf{f}_{3} \\
\mathbf{f}_{4} \\
\mathbf{f}_{5} \\
\mathbf{f}_{6} \\
\mathbf{f}_{7} \\
\mathbf{f}_{8}
\end{array}\right)\left(\begin{array}{lllllllll}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & -\xi_{1,1} & -\xi_{2,1} \\
0 & 0 & 0 & 1 & 0 & 0 & -\xi_{1,2} & -\xi_{2,2} \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & & 1
\end{array}\right)\left(\begin{array}{l}
\mathbf{d}_{1} \\
\mathbf{d}_{2} \\
\mathbf{d}_{3} \\
\mathbf{d}_{4} \\
\mathbf{d}_{5} \\
\mathbf{f}_{3} \\
\mathbf{f}_{4}^{*} \\
\mathbf{f}_{5}^{*} \\
\mathbf{f}_{6}^{*} \\
\mathbf{f}_{6}^{*} \\
\mathbf{f}_{7}^{*} \\
\mathbf{f}_{8}^{*}
\end{array}\right) \\
&\left(\begin{array}{l}
\mathbf{f}_{6}^{*} \\
\mathbf{d}_{7} \\
\mathbf{d}_{8}
\end{array}\right) \\
& \hline
\end{aligned}=\left(\begin{array}{llllllll}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & \xi_{1,1} & \xi_{1,2} & 0 & 0 & 1 & 0 \\
0 & 0 & \xi_{2,1} & \xi_{2,2} & 0 & 0 & 0 & 1
\end{array}\right)\left(\begin{array}{l}
\mathbf{d}_{1}^{*} \\
\mathbf{d}_{2}^{*} \\
\mathbf{d}_{3}^{*} \\
\mathbf{d}_{4}^{*} \\
\mathbf{d}_{5}^{*} \\
\mathbf{d}_{6}^{*} \\
\mathbf{d}_{7}^{*} \\
\mathbf{d}_{8}^{*}
\end{array}\right) .
$$

It is easy to verify that $\mathbb{F}$ and $\mathbb{F}^{*}$ are also dual orthonormal, and are distributed the same as $\mathbb{D}$ and $\mathbb{D}^{*}$.

Then the public parameters, challenge ciphertext, and queried secret keys, $\left(\mathrm{mpk}, \mathrm{CT}_{\sigma_{\beta}^{*}}^{(\mathrm{SF})},\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)$ in $\mathrm{Game}_{\nu}$ are expressed over bases $\mathbb{D}$ and $\mathbb{D}^{*}$ as

$$
\begin{aligned}
& m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{d}_{1}}, g_{1}^{\mathbf{d}_{2}}, g_{2}^{\mathbf{d}_{\mathbf{1}}^{*}}, g_{2}^{\mathbf{d}_{\mathbf{2}}^{*}}, g_{2}^{\mathbf{d}_{3}^{*}}, g_{2}^{\mathbf{d}_{4}^{*}}\right\}, \\
& \mathrm{CT}_{\sigma_{\beta}^{*}}^{(\mathrm{SF})}:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\eta}\right)^{s}, \mathrm{C}_{0}=g_{2}^{s\left(\mathbf{d}_{3}^{*}+\sigma_{\beta}^{*} \mathbf{d}_{4}^{*}\right)+\left[s_{7} \mathbf{d}_{7}^{*}+s_{8} \mathbf{d}_{8}^{*}\right]}\right\}, \\
& \mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}:=\left\{g_{1}^{\eta \mathbf{d}_{3}+r_{\ell}\left(\sigma_{\ell} \mathbf{d}_{3}-\mathbf{d}_{4}\right)+\left[r_{7, \ell} \mathbf{d}_{7}+r_{8, \ell} \mathbf{d}_{8}\right]}\right\}_{\ell \in[\nu]} .
\end{aligned}
$$

Then we can express them over bases $\mathbb{F}$ and $\mathbb{F}^{*}$ as

$$
\begin{aligned}
& m p k:=\left\{\mathbb{G} ; \alpha, g_{T}^{\alpha}, g_{T}^{\eta}, g_{1}^{\mathbf{f}_{1}}, g_{1}^{\mathbf{f}_{2}}, g_{2}^{\mathbf{f}_{1}^{*}}, g_{2}^{\mathbf{f}_{2}^{*}}, g_{2}^{\mathbf{f}_{3}^{*}}, g_{2}^{\mathbf{f}_{4}^{*}}\right\}, \\
& \mathrm{CT}_{\sigma_{\mathrm{R}}}^{(\mathrm{R})}:=\left\{\mathrm{C}=m \cdot\left(g_{T}^{\eta}\right)^{s}, \mathrm{C}_{0}=g_{2}^{s_{3} \mathbf{f}_{3}^{*}+s_{4} \mathbf{4}_{4}^{\mathbf{*}}+\left[s_{7} \mathbf{f}_{7}^{*}+s_{8} \mathbf{f}_{8}^{*}\right]}\right\}, \\
& \operatorname{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}:=\left\{g_{1}^{\eta \mathbf{f}_{3}+r_{\ell}\left(\sigma_{\ell} \mathbf{f}_{3}-\mathbf{f}_{4}\right)+\left[r_{7, \mathbf{f}_{7}^{\prime}+r_{8, \ell}^{\prime}}^{\prime} \mathbf{f}_{8}\right]}\right\}_{\ell \in[\nu]} .
\end{aligned}
$$

where

$$
\begin{aligned}
& s_{3}:=s-s_{7} \xi_{1,1}-s_{8} \xi_{2,1}, \\
& s_{4}:=s \sigma_{\beta}^{*}-s_{7} \xi_{1,2}-s_{8} \xi_{2,2}, \\
& \left\{\begin{array}{l}
r_{7, \ell}^{\prime}:=r_{7, \ell}+\eta \xi_{1,1}+r_{\ell}\left(\sigma_{\ell} \xi_{1,1}-\xi_{1,2}\right) \\
r_{8, \ell}^{\prime}:=r_{8, \ell}+\eta \xi_{2,1}+r_{\ell}\left(\sigma_{\ell} \xi_{2,1}-\xi_{2,2}\right)
\end{array}\right\}_{\ell \in[\nu]},
\end{aligned}
$$

which are all uniformly distributed if $\left(s_{7}, s_{8}\right)$ defined in Equation 9 is a non-zero vector since $s,\left\{\xi_{i, j}\right\}_{i \in[2], j \in[2]},\left\{r_{7, \ell}, r_{8, \ell}\right\}_{\ell \in[\nu]}$ are all uniformly picked from $\mathbb{Z}_{q}$.

In other words, the coefficients $s\left(1, \sigma_{\beta}^{*}\right)$ of $\mathbf{d}_{3}, \mathbf{d}_{4}$ in the $C_{0}$ term of the challenge ciphertext is changed to random coefficients $\left(s_{3}, s_{4}\right) \in \mathbb{Z}_{q}^{n}$ of $\mathbf{f}_{3}, \mathbf{f}_{4}$, thus the challenge ciphertext can be viewed as a semi-functional encryption of a random message in $G_{T}$ and under a random identity in $\mathbb{Z}_{q}$. Moreover, all coefficients $\left\{\left(r_{7, \ell}^{\prime}, r_{8, \ell}^{\prime}\right)\right\}_{\ell \in[\nu]}$ of $\mathbf{f}_{7}, \mathbf{f}_{8}$ in the $\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}$ are all uniformly distributed since $\left\{\left(r_{7, \ell}, r_{8, \ell}\right\}_{\ell \in[\nu]}\right.$ of $\mathbf{d}_{7}, \mathbf{d}_{8}$ are all independent random values. Thus

$$
\left(\mathrm{mpk}, \mathrm{CT}_{\sigma_{\beta}^{*}}^{(\mathrm{SF})},\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

expressed over bases $\mathbb{F}$ and $\mathbb{F}^{*}$ is properly distributed as

$$
\left(\mathrm{mpk}, \mathrm{CT}_{\sigma_{\mathrm{R}}}^{(\mathrm{R})},\left\{\mathrm{sk}_{\sigma_{\ell}}^{(\mathrm{SF})}\right\}_{\ell \in[\nu]}\right)
$$

in Game ${ }_{\text {Final }}$.
In the adversary's view, both $\left(\mathbb{D}, \mathbb{D}^{*}\right)$ and $\left(\mathbb{F}, \mathbb{F}^{*}\right)$ are consistent with the same public parameters. Therefore, the challenge ciphertext and queried secret keys above can be expressed as keys and ciphertext in two ways, in Game $\nu_{\nu}$ over bases $\left(\mathbb{D}, \mathbb{D}^{*}\right)$ and in $G^{2 m e m e}$ Final over bases $\left(\mathbb{F}, \mathbb{F}^{*}\right)$. Thus, $\mathrm{Game}_{\nu}$ and Game Final are statistically indistinguishable except with probability $1 / q$ (namely, the case $\left.\left(s_{7}, s_{8}\right)=\mathbf{0}\right)$.

Lemma 11. For any adversary $\mathcal{A}, \operatorname{Adv}_{\mathcal{A}}^{\operatorname{Game}_{\text {Final }}}(\lambda)=0$.
Proof. The value of $\beta$ is independent from the adversary's view in $G^{\text {ameme }}{ }_{\text {Final }}$. Hence, $\operatorname{Adv}_{\mathcal{A}}^{\text {Game }_{\text {Final }}}(\lambda)=0$.

In Game ${ }_{\text {Final }}$, the challenge ciphertext is a semi-functional encryption of a random message in $G_{T}$ and under a random identity in $\mathbb{Z}_{q}$, independent of the two messages and the challenge identities provided by $\mathcal{A}$. Thus, this IBE scheme is fully secure under the Symmetric External Diffie-Hellman assumption. Theorem 3 actually proves that this IBE scheme is fully secure and anonymous, but the security of a trivial IBE is sufficient and anonymity is not required.
