#### Abstract

Shadow is a lightweight block cipher proposed at IEEE IoT journal 2021. Shadow's main design principle is adopting a variant 4branch Feistel structure in order to provide a fast diffusion rate. We define such a structure as Shadow structure and prove that it is almost identical to the Generalized Feistel Network, which invalidates the design principle. Moreover, we give a structural distinguisher that can distinguish Shadow structure from random permutation with only two plaintext/ciphertext pairs. By exploiting the key schedule, the distinguisher can be extended to key recovery attack with only one plaintext/ciphertext pair. Furthermore, by considering Shadow's round function, only certain forms of monomials can appear in the ciphertext, resulting in an integral distinguisher of four plaintext/ciphertext pairs. Even more, the algebraic degree does not increase more than 12 for Shadow-32 and 20 for Shadow-64 regardless of rounds used. Our results show that Shadow is highly vulnerable to algebraic attacks, and that algebraic attacks should be carefully considered when designing ciphers with AND, rotation, and XOR operations.

Keywords: Block cipher, algebraic attack, cube attack

## 1 Introduction

The rapid advancement of digital technology and the internet has ushered in the era of the Internet of Things (IoT), where various devices are interconnected and interact with each other. In this IoT environment, security issues are becoming increasingly important as wireless communication and data exchange become prevalent. Additionally, traditional encryption techniques are facing challenges due to their heavy processing tasks and high costs, making them less efficient.

In response to this situation, numerous lightweight block ciphers are gaining attention. Lightweight block ciphers offers high security with minimal resources, ensuring efficient processing speed and low energy consumption compared to conventional encryption techniques. As a result, it has become even more critical in the IoT environment to maintain security while efficiently managing resources. A variety of lightweight block ciphers, such as Midori[1], PRESENT[5], HIGHT[14], GIFT[2], SIMON and SPECK[3], LEA[13], SKINNY[4], PIPO[16], PRINCE[6], LED[11], have been introduced in the literature and Shadow[12] is one of them.

Shadow is a lightweight block cipher whose round function consists of AND, Rotation, and XOR (AND-RX) operations. Shadow uses a variant of the generalized Feistel structure and the designers claim that their new logical combination method of AND-RX operations improves the diffusion rate of AND-RX ciphers.

A well-designed symmetric-key cipher should appear in a large number of monomials and have a high algebraic degree. Failure to do so makes it vulnerable to algebraic attacks using Gröbner basis[9], XL algorithms[8], as well as higherorder differential attacks [17], interpolation attacks [15], cube attacks [10]. In general, algebraic degree of block size increases with the number of rounds, reaching a maximum degree of (block size -1 ) in a given round. The complexity of an algebraic attack is usually calculated with the assumption that all possible monomials can appear, so the complexity of the attack increases exponentially as the degree increases, making the attacks impossible. An upper bound of the algebraic degree of a block cipher can be computed based on [7].

### 1.1 Our Contribution

1. Structural Distinguisher for Shadow Structure. We define a Shadow structure (Figure 1 in Appendix A) which is a generalization of Shadow by replacing the AND-RX update function (Figure 2 in Appendix A) to an arbitrary function $F$. We then show that the Shadow structure is almost equivalent to the 4 -branch Generalized Feistel Network by transforming it, and shows that Shadow's main design principle for fast diffusion does not work and even allows a full-round ${ }^{5}$ distinguisher. The structural distinguisher can distinguish Shadow structure from random permutation with only two plaintext/ciphertext pairs. The distinguisher can be extended to low data key recovery attack that only needs one plaintext/ciphertext pair by exploiting the key schedule.
2. Algebraic Weakness on Shadow. Considering Shadow's AND-RX structure update function, we prove that only certain forms of monomials can appear in ciphertext, leading to a very weak algebraic property. This allows us to find a low data integral distinguisher that only needs four ciphertexts. Also we theoretically computed upper bounds of the algebraic degree for

[^0]full-round Shadow-32 and Shadow-64; $12(\leq 31)$ and $20(\leq 63)$, respectively. This means that the full-round ciphers have the algebraic degree much less than (block size -1 ) giving algebraic weakness. All of the above results are experimentally verified and especially, the evaluation result that the algebraic degree of full-round Shadow-32 can reach up to 12 shows that the upper bound on the algebraic degree is tight.

### 1.2 Organization

Section 2 introduces block cipher Shadow, Shadow structure, and notations needed. In Section 3, we give a structural distinguisher and extend it to key recovery attacks by exploiting the key schedule. In Section 4, we show the algebraic weakness of Shadow, present integral distinguisher, and provide upper bound of algebraic degree of shadow. We conclude the paper in Section 5

## 2 Preliminary

This chapter introduces the block cipher Shadow and defines the Shadow structure.

### 2.1 Boolean Functions and Vectorial Boolean Functions

A Boolean function $f$ on $n$ variables is a function from $\mathbb{F}_{2}^{n}$ to $\mathbb{F}_{2} . f$ can be represented by a polynomial on $n$ variables over $\mathbb{F}_{2}$, called algebraic normal form(ANF). The algebraic degree of $f$, denoted by $\operatorname{deg}(f)$, is defined as the degree of its ANF. $f$ is called linear if $\operatorname{deg}(f) \leq 1$. A $(m, n)$-vectorial Boolean function $F$ is a function from $\mathbb{F}_{2}^{m}$ to $\mathbb{F}_{2}^{n}$ and algebraic degree of $F$ is defined as the highest degree of its coordinates. For vectorial Boolean function $F=$ $\left(f_{0}, f_{1}, \ldots, f_{n-1}\right), G=\left(g_{0}, g_{1}, \ldots, g_{n-1}\right)$, we write $F \mid G$ if there exist a Boolean function $h_{i}$ s.t $h_{i} f_{i}=g_{i}$ for all $0 \leq i<n$

### 2.2 Cube Attack

let $k=\left(k_{1}, \ldots, k_{n}\right)$ and $v=\left(v_{1}, \ldots, v_{m}\right)$ be a $n$ secret variable and $m$ public variables, respectively. Then each bit of symmetric-key cryptosystem can be represented as Boolean function $f(k, v)$. In our case, $k$ will denote masterkey of block cipher and $v$ will denote plaintext and $f(k, v)$ will denote each bit of ciphertext.

Let a set of public variables $I=\left\{v_{i_{1}}, v_{i_{1}}, \ldots, v_{i_{d}}\right\}$ be a set of cube variables. Then $f(k, v)$ can be rewritten as

$$
f(k, v)=t_{I} \cdot p_{I}(k, v) \oplus q_{I}(k, v)
$$

where $t_{I}=\prod_{v \in I} v$ and $p_{I}$ does not contain any variable in $I$, and each term in $q_{I}$ is not divisible by $t_{I}$.

Let $C_{I}$, which is referred as a cube, be a set of $2^{|I|}$ values where variables in $I$ are taking all possible combinations of values, and all remaining variables are fixed to some arbitrary vales. Then following equation holds.

$$
\bigoplus_{\left(v_{i_{1}}, v_{i_{1}}, \ldots, v_{i_{d}}\right) \in\{0,1\}^{d}} f(k, v)=p_{I}(k, v)
$$

We will mainly use the fact that if $f(x, v)$ does not contain a multiple of $t_{I}$, then $p(x, v)=0$ which is usually called integral distinguisher.

### 2.3 Notations

$$
\begin{aligned}
\& & : \text { bitwise } A N D(\text { can be omitted }) \\
\oplus & : \text { bitwise } X O R \\
S^{j}(x) & : j \text {-bit left rotation of } x \\
S^{I}(x) & :=\prod_{j \in I} S^{j}(x) \\
x[n] & : n \text {-th bit of } x(\text { counted from } 0)
\end{aligned}
$$

### 2.4 Specification of Block Cipher Shadow

Shadow is a block cipher suggested in [12] which is based on variant of 4 -branch generalized Feistel structure. Shadow-32 uses 32 -bit block size and 64 -bit key, and Shadow-64 uses 64 -bit block size and 128-bit key. Round number (RN) is 16 and 32 , respectively.

Shadow Structure Before defining block cipher Shadow, we first define the Shadow structure (Figure 1 in Appendix A) that restricts the Shadow's update function to an arbitrary function $F$. For round key $K_{0}, K_{1}, K_{2}, K_{3} \in\{0,1\}^{n}$ and update function $F:\{0,1\}^{n} \rightarrow\{0,1\}^{n}$, Round function for Shadow structure is $R^{0} \circ R^{1}$ where

$$
\begin{gathered}
R^{0}, R^{1}:\{0,1\}^{n \times 4} \rightarrow\{0,1\}^{n \times 4} \\
R^{0}(A, B, C, D)=\left(B \oplus F(A) \oplus K_{0}, B, D \oplus F(C) \oplus K_{1}, C\right) \\
R^{1}(A, B, C, D)=\left(C, B \oplus F(A) \oplus K_{2}, A, D \oplus F(C) \oplus K_{3}\right)
\end{gathered}
$$

We define the input of the $i$-round $R^{0}, R^{1}$ as $L_{0}^{i-1}\left\|L_{1}^{i-1}\right\| R_{0}^{i-1} \| R_{1}^{i-1}$ and $M_{0}^{i-1}\left\|M_{1}^{i-1}\right\| N_{0}^{i-1} \| N_{1}^{i-1}$, divided into four $n$-bit branches, respectively. We also define $i$-round roundkey for $R^{0}, R^{1}$ as $K_{L}^{i-1}, K_{R}^{i-1}$ and $K_{M}^{i-1}, K_{N}^{i-1}$ respectively.

Block Cipher Shadow Shadow uses the AND-RX update function $F(x)=$ $S^{a}(x) \& S^{b}(x) \oplus S^{c}(x)$ where $a=1, b=7, c=2$ and $n=8$ for Shadow-32 and $n=16$ for Shadow-64 (Figure 2 in Appendix A). Shadow-32 and Shadow-64 use generator 1 and generator 2 as their key schedules respectively and consist of Addroundconstant, NX, and permutation. Masterkey $K$ is represented by $k_{0}\left\|k_{1}\right\| k_{2}\|\cdots\| k_{62} \| k_{63}$ or $k_{0}\left\|k_{1}\right\| \cdots\left\|k_{126}\right\| k_{127}$ and the round number $r$ is used as the round constant and are represented by $c_{0}\left\|c_{1}\right\| c_{2}\left\|c_{3}\right\| c_{4}$ or $c_{0}\left\|c_{1}\right\| c_{2}\left\|c_{3}\right\| c_{4} \| c_{5}$.

## 1. generator 1

Round function of generator 1 consist of the following operations and uses the upper 32 bits after the round function as the round key.

## (a) Addroundconstant

Addroundconstant XORs 5-bit $k_{3}\left\|k_{4}\right\| k_{5}\left\|k_{6}\right\| k_{7}$ with round constant $c_{0}\left\|c_{1}\right\| c_{2}\left\|c_{3}\right\| c_{4}$.
(b) $\mathbf{N X}$

NX is an operation applied to 8 -bit $k_{56}\left\|k_{57}\right\| \cdots\left\|k_{62}\right\| k_{63}$ and is represented as follows.

$$
\begin{aligned}
k_{56}^{\prime} & =k_{56} \&\left(k_{56} \oplus k_{62}\right) \\
k_{57}^{\prime} & =k_{57} \&\left(k_{57} \oplus k_{63}\right) \\
k_{58}^{\prime} & =k_{58} \&\left(k_{58} \oplus k_{56} \oplus k_{62}\right) \\
k_{59}^{\prime} & =k_{59} \&\left(k_{59} \oplus k_{57} \oplus k_{63}\right) \\
k_{60}^{\prime} & =k_{60} \&\left(k_{60} \oplus k_{58} \oplus k_{56} \oplus k_{62}\right) \\
k_{61}^{\prime} & =k_{61} \&\left(k_{61} \oplus k_{59} \oplus k_{57} \oplus k_{63}\right) \\
k_{62}^{\prime} & =k_{62} \&\left(k_{62} \oplus k_{60} \oplus k_{58} \oplus k_{56} \oplus k_{62}\right) \\
k_{63}^{\prime} & =k_{63} \&\left(k_{63} \oplus k_{61} \oplus k_{59} \oplus k_{57} \oplus k_{63}\right)
\end{aligned}
$$

(c) permutation

This operation is the permutation according to Table 4 in Appendix A.
2. generator 2 Round function of generator 2 consists of the following operations and uses the upper 64 bits after the round function as the round key.
(a) Addroundconstant

Addroundconstant XORs 6 -bit $k_{2}\left\|k_{3}\right\| k_{4}\left\|k_{5}\right\| k_{6} \| k_{7}$ with round constant $c_{0}\left\|c_{1}\right\| c_{2}\left\|c_{3}\right\| c_{4} \| c_{5}$.
(b) $\mathbf{N X}$

NX is an operation applied to 24 -bit $k_{104}\left\|k_{105}\right\| \cdots\left\|k_{126}\right\| k_{127}$ and is
represented as follows.

$$
\begin{aligned}
k_{104}^{\prime} & =k_{104} \&\left(k_{104} \oplus k_{126}\right) \\
k_{105}^{\prime} & =k_{105} \&\left(k_{105} \oplus k_{127}\right) \\
k_{106}^{\prime} & =k_{106} \&\left(k_{106} \oplus k_{104} \oplus k_{126}\right) \\
k_{107}^{\prime} & =k_{107} \&\left(k_{107} \oplus k_{105} \oplus k_{127}\right) \\
k_{108}^{\prime} & =k_{108} \&\left(k_{108} \oplus k_{106} \oplus k_{104} \oplus k_{126}\right) \\
k_{109}^{\prime} & =k_{109} \&\left(k_{109} \oplus k_{107} \oplus k_{105} \oplus k_{127}\right) \\
k_{110}^{\prime} & =k_{110} \&\left(k_{110} \oplus k_{108} \oplus k_{106} \oplus k_{104} \oplus k_{126}\right) \\
\vdots & \\
k_{127}^{\prime} & =k_{127} \&\left(k_{127} \oplus k_{125} \oplus k_{123} \oplus \cdots \oplus k_{105} \oplus k_{127}\right)
\end{aligned}
$$

(c) permutation

This operation is the permutation according to Table 5 in Appendix A.

## 3 Structural Attack on Shadow Structure

### 3.1 Practical Distinguisher of Shadow Structure with Probability 1

Shadow's encryption function can be re-expressed as $\left(R^{0} \circ R^{1}\right)^{n}=R^{0} \circ\left(R^{1} \circ\right.$ $\left.R^{0}\right)^{n-1} \circ R^{1}$. If we expand $R^{1} \circ R^{0}$, we get

$$
\begin{array}{r}
R^{1} \circ R^{0}\left(M_{0}^{i}, M_{1}^{i}, N_{0}^{i}, N_{1}^{i}\right)=\left(M_{1}^{i} \oplus F\left(M_{0}^{i}\right) \oplus F\left(N_{0}^{i}\right) \oplus K_{L}^{i+1} \oplus\right. \\
\left.K_{M}^{i}, N_{0}^{i}, N_{1}^{i} \oplus F\left(M_{0}^{i}\right) \oplus f\left(N_{0}^{i}\right) \oplus K_{R}^{i+1} \oplus K_{N}^{i}, M_{0}^{i}\right) \tag{1}
\end{array}
$$

Thus, contrary to the author's claim that using two $F$ functions per round in both directions makes fast diffusion, Shadow structure is just a branch permutation of the GFN type 2 except for the first and last rounds. We can also see from the equality (1) that

$$
\begin{align*}
& M_{0}^{i+1} \oplus N_{0}^{i+1}=M_{1}^{i} \oplus N_{1}^{i} \oplus K_{M}^{i} \oplus K_{N}^{i} \oplus K_{L}^{i+1} \oplus K_{R}^{i+1} \\
& M_{1}^{i+1} \oplus N_{1}^{i+1}=M_{0}^{i} \oplus N_{0}^{i} \tag{2}
\end{align*}
$$

Applying the equality (2) iteratively, we get

$$
\begin{align*}
& M_{i-1 \bmod 2}^{i} \oplus N_{i-1 \bmod 2}^{i}=M_{1}^{0} \oplus N_{1}^{0} \oplus A^{i} \\
& M_{i \bmod 2}^{i} \oplus N_{i \bmod 2}^{i}=M_{0}^{0} \oplus N_{0}^{0} \oplus B^{i} \\
& \text { where } A^{i}=\sum_{j=0}^{\lfloor(i-1) / 2\rfloor} K_{M}^{2 j} \oplus K_{N}^{2 j} \oplus K_{L}^{2 j+1} \oplus K_{R}^{2 j+1} \\
& \text { and } B^{i}=\sum_{j=1}^{\lfloor i / 2\rfloor} K_{M}^{2 j-1} \oplus K_{N}^{2 j-1} \oplus K_{L}^{2 j} \oplus K_{R}^{2 j} \tag{3}
\end{align*}
$$

Substituting the equality 3 for $L, R$, we get following equalities.

$$
\begin{array}{ll}
L_{0}^{i} \oplus R_{0}^{i} \oplus L_{0}^{0} \oplus R_{0}^{0}=A^{i} & \text { if } i \text { is even, } \\
L_{0}^{i} \oplus R_{0}^{i} \oplus F\left(L_{0}^{0}\right) \oplus F\left(R_{0}^{0}\right) \oplus L_{1}^{0} \oplus R_{1}^{0}=B^{i} \oplus K_{L}^{0} \oplus K_{R}^{0} & \\
& \\
L_{1}^{i} \oplus R_{1}^{i} \oplus F\left(L_{0}^{i}\right) \oplus F\left(R_{0}^{i}\right) \oplus L_{0}^{0} \oplus R_{0}^{0}=A^{i} \oplus K_{M}^{i-1} \oplus K_{N}^{i-1} & \text { if } i \text { is } o d d, \\
L_{1}^{i} \oplus R_{1}^{i} \oplus L_{1}^{0} \oplus R_{1}^{0} \oplus F\left(L_{0}^{i}\right) \oplus F\left(R_{0}^{i}\right) \oplus F\left(L_{0}^{0}\right) \oplus F\left(R_{0}^{0}\right) &  \tag{5}\\
=B^{i} \oplus K_{L}^{0} \oplus K_{R}^{0} \oplus K_{M}^{i-1} \oplus K_{N}^{i-1} &
\end{array}
$$

Thus, given only 2 plaintext and ciphertext pairs, we can distinguish a random permutation from a Shadow structure with advantage $1-2^{-2 n}$ by checking that the left-hand side of the equation (4) or (5) matches according to the parity of $i$. However, even if we guess the round keys of the first or last rounds, right-side of the equation (4) or (5) only gives us the information of sum of the round keys. So it is not trivial to extend the above distinguisher to key recovery attacks.

### 3.2 Key recovery Attack on Shadow Structure

If the keyschedule is known, the master key can be recovered with only single ciphertext/plaintext pair by first filtering out possible keys based on the keyschedule, and then exhaustively searching the remaining keys. The attack Procedure and its complexity is as follows( $k$ denotes the length of masterkey).

1. checking keyschedule Compute the right-hand side of the equation (4) or (5) through the given ciphertext/plaintext pair. Then filter out only the master keys that can generate it. There are two ways to filter out the master key depending on the (non-)linearity of the keyschedule.
(a) nonlinear keyschedule

Just bruteforce the masterkey on the keyschedule. If we define the complexity of computing a keyschedule once as $C_{k s}$, the complexity is $C_{k s} \times$ $2^{k}$.
(b) linear keyschedule

Represent the right-side of the equation (4) or (5) as an equation of the master key, and solve the equation. Since the complexity of solving linear equations is relatively negligible, we ignore this complexity.
2. Bruteforce remaining masterkeys Since the expected number of remaining masterkey is $2^{k-2 n}$, the complexity is $C_{e n c} \times 2^{k-2 n}$ if we define the complexity of one encryption as $C_{\text {enc }}$

If $C_{e n c} \gg C_{k s}$, which is the majority case, we can recover masterkey with lower complexity than exhaustive search. In particular, if the keyschedule is linear, we can recover the master key with much low complexity $C_{e n c} \times 2^{k-2 n}$.

## 4 Algebraic Weakness on Shadow

Shadow ciphers have the additional weakness that only certain forms of monomials can appear on the ANF of ciphertext due to the AND-RX structure of $F$ function. In this chapter, we present a theoretical proof and experimental results for this. Throughout this chapter, we assume that key is fixed and regard each branch as a vectorial Boolean function of plaintext only. Also, we assume that $n=16$ and $a, b$ are odd, which coincides to the parameter of Shadow-32. However, $n$ can be easily generalized to any even number.

### 4.1 Possible Monomials on Shadow

Define $X_{0}$ and $X_{1}$ as follows

$$
\begin{aligned}
& X_{0}=M_{0}^{0} \oplus N_{0}^{0} \\
& X_{1}=M_{1}^{0} \oplus N_{1}^{0}
\end{aligned}
$$

By modifying the equality (2), we can get following equation

$$
\begin{equation*}
M_{0}^{i} \oplus N_{0}^{i}=X_{i} \bmod 2 \oplus C^{i} \tag{6}
\end{equation*}
$$

where $C^{i}=\left\{\begin{array}{ll}B^{i} & \text { if } i \text { is even } \\ A^{i} & \text { if } i \text { is odd }\end{array}\right.$.
Using the equality (6), we can expand first element of equality (1) as follows.

$$
\begin{align*}
& M_{0}^{i+1} \oplus K_{L}^{i+1} \oplus K_{M}^{i} \\
& =f\left(M_{0}^{i}\right) \oplus f\left(N_{0}^{i}\right) \oplus M_{1}^{i} \\
& =S^{a}\left(M_{0}^{i}\right) S^{b}\left(M_{0}^{i}\right) \oplus S^{a}\left(N_{0}^{i}\right) S^{b}\left(N_{0}^{i}\right) \oplus S^{c}\left(M_{0}^{i}\right) \oplus S^{c}\left(N_{0}^{i}\right) \oplus M_{1}^{i} \\
& = \\
& S^{a}\left(M_{0}^{i}\right) S^{b}\left(M_{0}^{i}\right) \oplus S^{a}\left(X_{i \bmod 2} \oplus M_{0}^{i} \oplus C^{i}\right) S^{b}\left(X_{\left.i \bmod 2 \oplus M_{0}^{i} \oplus C^{i}\right)}\right. \\
& \quad \oplus S^{c}\left(X_{i \bmod 2} \oplus C^{i}\right) \oplus N_{0}^{i-1} \\
& = \\
& S^{a}\left(M_{0}^{i}\right) S^{b}\left(X_{i \bmod 2}\right) \oplus S^{a}\left(X_{i \bmod 2}\right) S^{b}\left(M_{0}^{i}\right) \oplus S^{a}\left(C^{i}\right) S^{b}\left(M_{0}^{i}\right) \\
&  \tag{7}\\
& \\
& \oplus S^{a}\left(M_{0}^{i}\right) S^{a}\left(C^{i}\right) \oplus M_{0}^{i-1} \oplus S^{a}\left(X_{i \bmod 2}\right) S^{b}\left(X_{i \bmod 2}\right) \oplus S^{a}\left(C^{i}\right) S^{b}\left(X_{i \bmod 2)}\right) \\
& \quad \oplus S^{a}\left(X_{i \bmod 2}\right) S^{a}\left(C^{i}\right) \oplus S^{c}\left(X_{i \bmod 2}\right) \\
& \quad \oplus X_{i-1 \bmod 2} \oplus S^{a}\left(C^{i}\right) S^{b}\left(C^{i}\right) \oplus S^{c}\left(C^{i}\right) \oplus C^{i-1}
\end{align*}
$$

Note that we can make similar equality for $M_{0}^{i}$.

Theorem 1. Let

$$
\begin{aligned}
& P_{0}=\left\{l \& S^{\{0,2,4,6\}}\left(X_{0}\right) S^{\{1,3,5,7\}}\left(X_{1}\right): l \text { is linear over } M_{0}^{0}, N_{0}^{0}, M_{1}^{0}, N_{1}^{0}\right\} \\
& P_{1}=\left\{l \& S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right): l \text { is linear over } M_{0}^{0}, N_{0}^{0}, M_{1}^{0}, N_{1}^{0}\right\}
\end{aligned}
$$

and define

$$
\operatorname{span}(S):=\left\{\sum_{i=1}^{k} \lambda_{i} \& v_{i}: k \in \mathbb{N}, v_{i} \in S, \lambda_{i} \in \mathbb{F}_{2}^{n}\right\}
$$

where $S$ is a set of ( $m$, $n$-vectorial Boolean functions), and

$$
L(S):=\operatorname{span}(\{p: \exists s \in S \text { s.t } p \mid s\})
$$

where $S$ is a set of vectorial Boolean functions. Then $M_{0}^{i}, N_{0}^{i} \in L\left(P_{i \bmod 2}\right)$ if $a, b$ are odd.

Proof. without loss of generality, we will prove for $M_{0}^{i}$. First we define following two properties.

1. interchangeability : $S^{a}, S^{b}$ will move the elements of $P_{i}$ to $P_{i+1} \bmod 2$
2. closedness : $L\left(P_{i}\right)$ is closed for the multiplication of $S^{a}\left(X_{i+1} \bmod 2\right)$ and $S^{b}\left(X_{i+1} \bmod 2\right)$ since $a, b$ are both odd

Based on the above properties, our proof proceeds with mathematical induction.

1. Base condition $(i=0)$ Trivially holds since $M_{0}^{0}$ itself is linear.
2. Base condition $(i=1)$ Holds if we put $i=0$ on the equality (7)
3. Inductive Step Assume that hypothesis holds for $i \leq k$. Then for $i=k+1$, it is enough to show that every term in (7) are in $L\left(P_{k+1} \bmod 2\right)$.
(a) $S^{a}\left(M_{0}^{k}\right) S^{b}\left(X_{k \bmod 2}\right)$ and $S^{a}\left(X_{k \bmod 2}\right) S^{b}\left(M_{0}^{k}\right)$

By induction hypothesis $M_{0}^{k} \in L\left(P_{k} \bmod 2\right)$ and thus both term are in $L\left(P_{k+1} \bmod 2\right)$ by the closedness and interchangeability.
(b) $S^{a}\left(C^{k}\right) S^{a}\left(M_{0}^{k}\right)$ and $S^{a}\left(M_{0}^{k}\right) S^{a}\left(C^{k}\right)$

By induction hypothesis $M_{0}^{k} \in L\left(P_{k \bmod 2}\right)$. Thus both terms are in $L\left(P_{k+1} \bmod 2\right)$ since $C^{k}$ is constant and interchangeability.
(c) $M_{0}^{k-1}$
$M_{0}^{k-1} \in L\left(P_{k+1} \bmod 2\right)$ by the induction hypothesis
(d) $S^{a}\left(X_{k \bmod 2}\right) S^{b}\left(X_{k \bmod 2}\right)$
$S^{a}\left(X_{k \bmod 2}\right) S^{b}\left(X_{k \bmod 2}\right) \in L\left(P_{k+1} \bmod 2\right)$ since $S^{a}\left(X_{k \bmod 2}\right)$ is a linear term.
(e) extra terms

They are all in $L\left(P_{k+1} \bmod 2\right)$ since they are all linear or constant term.

From theorem 1, we can see the vulnerability that only elements of $L\left(P_{0}\right)$ or $L\left(P_{1}\right)$ can appear on the ciphertext. This vulnerability allows us to derive the following low data integral distinguisher.

Corollary 1. For even $r, e_{0}, e_{1}$ and odd o, $L_{0}^{r}[o]$ does not contain $L_{1}^{0}\left[e_{0}\right] L_{1}^{0}\left[e_{1}\right]$ or it's multiples. Therefore for a cube variables $I=\left\{L_{1}^{0}\left[e_{0}\right], L_{1}^{0}\left[e_{1}\right]\right\}$,

$$
\bigoplus_{C_{I}} L_{0}^{r}[o]=0
$$

i.e, I forms a integral distinguisher

Proof. By Theorem 1, $L_{0}^{r}=N_{0}^{r-1} \in L\left(P_{1}\right)$ and remember that

$$
\begin{aligned}
& P_{1}=\left\{l \& S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right): l \text { is linear over } M_{0}^{0}, N_{0}^{0}, M_{1}^{0}, N_{1}^{0}\right\} \\
& X_{0}=N_{0}^{0} \oplus M_{0}^{0}=L_{1}^{0} \oplus R_{1}^{0} \oplus F\left(L_{0}^{0}\right) \oplus F\left(R_{0}^{0}\right) \oplus K_{L}^{0} \oplus K_{R}^{0} \\
& X_{1}=N_{1}^{0} \oplus M_{1}^{0}=L_{0}^{0} \oplus R_{0}^{0}
\end{aligned}
$$

Therefore except the arbitrary linear term $l, L_{1}^{0}$ can only lies on $S^{1}\left(X_{0}\right) S^{3}\left(X_{0}\right) S^{5}\left(X_{0}\right) S^{7}\left(X_{0}\right)$. Since $a, b$ are both odd, the odd bits of $L_{1}^{0}$ cannot affect the odd bits of $S^{1}\left(X_{0}\right) S^{3}\left(X_{0}\right) S^{5}\left(X_{0}\right) S^{7}\left(X_{0}\right)$. Thus, even if we consider $l$, $L_{r}^{0}$ does not include $L_{1}^{0}\left[e_{0}\right] L_{1}^{0}\left[e_{1}\right]$ and its multiples. Other cases when the parity of the round and cube indices is changed are listed in Table 1.

Table 1. Cube variables with integral bits

| Round | Cube variables for $L_{1}^{0}, R_{1}^{0}$ | Integral bits for $L_{0}^{r}, R_{0}^{r}$ |
| :---: | :---: | :---: |
| even | any two even bits | odd |
| even | any two odd bits | even |
| odd | any two even bits | even |
| odd | any two odd bits | odd |

From theorem 1, we can also derive the non-trivial upper bound of algebraic degree for each branch of Shadow.

Corollary 2. For arbitrary round r, upper bound of algebraic degree of each branch can computed as follows if $a, b$ are odd.

$$
\begin{aligned}
& \operatorname{deg}\left(L_{0}^{r}\right), \operatorname{deg}\left(R_{0}^{r}\right) \leq 2+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right) \\
& \operatorname{deg}\left(L_{1}^{r}\right), \operatorname{deg}\left(R_{1}^{r}\right) \leq 4+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)
\end{aligned}
$$

Proof. We will assume that $r$ is even and give proofs for $L_{0}^{r}, L_{1}^{r}$. Other cases can also be proved similarly.

## 1. proof for $L_{0}^{r}$

By Theorem 1, $L_{0}^{r}=N_{0}^{r-1} \in L\left(P_{r-1 \bmod 2}\right)=P_{1}$. Thus

$$
\begin{aligned}
\operatorname{deg}\left(L_{0}^{r}\right) & \leq \operatorname{deg}\left(l \& S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right) \\
& \leq \operatorname{deg}(l)+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right) \\
& \leq 2+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)
\end{aligned}
$$

Note that $\operatorname{deg}(l)=2$ since we consider it as a variable of $L_{0}^{0}, L_{1}^{0}, R_{0}^{0}, R_{1}^{0}$.
2. proof for $L_{1}^{r}$
since

$$
\begin{aligned}
L_{1}^{r} & =M_{1}^{r-1} \oplus F\left(M_{0}^{r-1}\right) \oplus K_{L}^{r-1} \\
& =N_{0}^{r-2} \oplus S^{a}\left(M_{0}^{r-1}\right) S^{b}\left(M_{0}^{r-1}\right) \oplus S^{c}\left(M_{0}^{r-1}\right) \oplus K_{L}^{r-1}
\end{aligned}
$$

We will compute the upper bound of degree part by part.
(a) $\operatorname{deg}\left(N_{0}^{r-2}\right)$
since $N_{0}^{r-2} \in L\left(P_{r \bmod 2}\right)=P_{0}$,

$$
\begin{aligned}
\operatorname{deg}\left(N_{0}^{r-2}\right) & \leq 2+\operatorname{deg}\left(S^{\{0,2,4,6\}}\left(X_{0}\right) S^{\{1,3,5,7\}}\left(X_{1}\right)\right) \\
& =2+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)
\end{aligned}
$$

(b) $\operatorname{deg}\left(S^{a}\left(M_{0}^{r-1}\right) S^{b}\left(M_{0}^{r-1}\right)\right)$
since $M_{0}^{r-1} \in L\left(P_{1}\right)$,
$S^{a}\left(M_{0}^{r-1}\right) S^{b}\left(M_{0}^{r-1}\right) \in L\left(\left\{l_{1} l_{2} \& S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right): l_{1}, l_{2}\right.\right.$
are linear over $\left.\left.M_{0}^{0}, N_{0}^{0}, M_{1}^{0}, N_{1}^{0}\right\}\right)$

$$
\begin{aligned}
\rightarrow \operatorname{deg}\left(S^{a}\left(M_{0}^{r-1}\right) S^{b}\left(M_{0}^{r-1}\right)\right. & \leq \operatorname{deg}\left(l_{1} l_{2}\right)+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right) \\
& \leq 4+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)
\end{aligned}
$$

Table 2. upper bound of algebraic degree for each branch of Shadow-32,64.

| Block size | Upper bound of algebraic degree |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $L_{0}^{r}$ | $L_{1}^{r}$ | $R_{0}^{r}$ | $R_{1}^{r}$ |
| 32 | $10^{*}$ | $12^{*}$ | $10^{*}$ | $12^{*}$ |
| 64 | 18 | 20 | 18 | 20 |

* means bound is tight
(c) $\operatorname{deg}\left(S^{c}\left(M_{0}^{r-1}\right)\right)$
since $S^{c}\left(M_{0}^{r-1}\right) \in L\left(P_{c+1 \bmod 2}\right)$, $\operatorname{deg}\left(S^{c}\left(M_{0}^{r-1}\right)\right) \leq 2+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)$
in summary,

$$
\begin{aligned}
\operatorname{deg}\left(L_{1}^{r}\right) & \leq \max \left(\operatorname{deg}\left(N_{0}^{r-2}\right), \operatorname{deg}\left(S^{a}\left(M_{0}^{r-1}\right) S^{b}\left(M_{0}^{r-1}\right)\right), \operatorname{deg}\left(S^{c}\left(M_{0}^{r-1}\right)\right)\right. \\
& \leq 4+\operatorname{deg}\left(S^{\{1,3,5,7\}}\left(X_{0}\right) S^{\{0,2,4,6\}}\left(X_{1}\right)\right)
\end{aligned}
$$

### 4.2 Results and Experimental Verification

Shadow-32 We computed each cubesum corresponding to Corollary 1 and checked the validity. Also, We computed the upper bound of algebraic degree according to Corollary 1. The results are given in table 2. Table 3 shows the maximum algebraic degree each round of Shadow-32 computed experimentally. From round 8 , the degree stops growing at 10,12 , showing that the upper bound of Corollary 2 is tight.

Shadow-64 We also computed the upper bound algebraic degree for Shadow64 . Since $n=16$ for Shadow-64, Corollary 2 should be modified as follows.

$$
\begin{aligned}
& \operatorname{deg}\left(L_{0}^{r}\right), \operatorname{deg}\left(R_{0}^{r}\right) \leq 2+\operatorname{deg}\left(S^{\{1,3,5,7,9,11,13,15\}}\left(X_{0}\right) S^{\{0,2,4,6,8,10,12,14\}}\left(X_{1}\right)\right) \\
& \operatorname{deg}\left(L_{1}^{r}\right), \operatorname{deg}\left(R_{1}^{r}\right) \leq 4+\operatorname{deg}\left(S^{\{1,3,5,7,9,11,13,15\}}\left(X_{0}\right) S^{\{0,2,4,6,8,10,12,14\}}\left(X_{1}\right)\right)
\end{aligned}
$$

The result is also given in table 2.

### 4.3 On the Key Recovery Attack

Through the above analysis, we confirmed that Shadow has an algebraic vulnerability and attempted a key recovery attack using the integral distinguisher of corollary 1 and guessing the first or last round key. However, due to the existence of distinguishers in all rounds, the equality of the corollary holds for all guessed keys, making the key recovery attack impossible. We leave the key recovery attack as a future work.

Table 3. Experimental result of algebraic degree of Shadow- 32 for each branch

| Round $(r)$ | Maximum algebraic degree |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $L_{0}^{r}$ | $L_{1}^{r}$ | $R_{0}^{r}$ | $R_{1}^{r}$ |
| 1 | 2 | 3 | 2 | 3 |
| 2 | 3 | 6 | 3 | 6 |
| 3 | 4 | 8 | 4 | 8 |
| 4 | 6 | 11 | 6 | 11 |
| 5 | 7 | 11 | 7 | 11 |
| 6 | 8 | 12 | 8 | 12 |
| 7 | 9 | 12 | 9 | 12 |
| 8 | 10 | 12 | 10 | 12 |
| 9 | 10 | 12 | 10 | 12 |
| 10 | 10 | 12 | 10 | 12 |
| 11 | 10 | 12 | 10 | 12 |
| 12 | 10 | 12 | 10 | 12 |
| 13 | 10 | 12 | 10 | 12 |

## 5 Conclusion

In this paper, we define the Shadow structure, a generalization of Shadow, and show that the structure is almost equivalent to the 4 -branch Gerenalized Feistel Network. Moreover, we give a low data structural distinguisher that can distinguish Shadow structure from random permutation with only two plaintext/ciphertext pairs. The distinguisher can be extended to key recovery attack with only one plaintext/ciphertext pair by exploiting the key schedule. We also prove that Shadow's AND-RX update function leads to an algebraic weakness that only certain forms of monomials appear. Based on that, we show that there is an integral distinguisher of cube size 2 and that algebraic degree cannot increase beyond 12 for Shadow- 32 and 20 for Shadow-64, regardless of the number of rounds. These strong algebraic vulnerabilities are thought to be due to the cancellation of higher-order monomials, and must be considered carefully when designing AND-RX structured ciphers. Since these properties are not easily identified at first glance, we would like to highlight that they might be negatively used as a backdoor for a block cipher.
