#### Abstract

Latin squares are a classical and well-studied topic of discrete mathematics, and recently Takeuti and Adachi (IACR ePrint, 2023) proposed $(2, n)$-threshold secret sharing based on mutually orthogonal Latin squares (MOLS). Hence efficient constructions of as large sets of MOLS as possible are also important from practical viewpoints. In this letter, we determine the maximum number of MOLS among a known class of Latin squares defined by weighted sums. We also mention some known property of Latin squares interpreted via the relation to secret sharing and a connection of Takeuti-Adachi's scheme to Shamir's secret sharing scheme. Keywords: Latin squares, upper bounds, secret sharing

## 1 Introduction

A Latin square of size $v \times v$ (where $v \geq 2$ ) is a $v \times v$ square array of integers from 0 to $v-1$ where each row/ column consists of every integer in the range $[0, v-1]$ appearing only once. Latin squares are a classical well-studied topic in discrete mathematics. One of the famous and efficient constructions of Latin squares is one using weighted sums with fixed weights; here we call them weighted-sum Latin squares.

Recently, Takeuti and Adachi [10] proposed a (2,n)-threshold secret sharing scheme based on mutually orthogonal Latin squares (MOLS). Secret sharing [5, 9] is a cryptographic technology to protect distributed data storage against both steals and deletion of data. By their result, efficient constructions of as large sets of MOLS as possible are important from not just theoretical but also practical viewpoints.

Let $M(v)$ and $M^{\mathrm{WS}}(v)$ denote, respectively, the maximum cardinalities of general MOLS and of MOLS consisting of weighted-sum Latin squares only (MOWSLS, in short) of size $v \times v$. A bound $M(v) \leq v-1$ for MOLS is well-known. On the other hand, for MOWSLS, it is obvious that $M^{\mathrm{WS}}(v) \leq M(v)$, and values of $M^{\mathrm{WS}}(v)$ are evaluated for small $v$ 's by computer experiments in [7]. The main result of this letter is the following that fully determines the value of $M^{\mathrm{WS}}(v)$ for any $v \geq 2$ (see Section 3.1 for the proof):

Theorem 1. Let $p_{0}$ be the smallest prime factor of $v \geq 2$. Then we have $M^{\mathrm{WS}}(v)=p_{0}-1$.
Hence, the maximum cardinality $v-1$ of MOLS is achievable by weighted-sum Latin squares when $v$ is a prime; while considering composite $v$ 's instead of prime ones has no advantage in generating large sets of MOWSLS.

We also mention some known properties of Latin squares and secret sharing, in connection to TakeutiAdachi's secret sharing scheme. First, we mention in Section 3.2 that the known bound $M(v) \leq v-1$ is also deduced by applying a known lower bound for share sizes in secret sharing schemes to TakeutiAdachi's scheme. Secondly, we point out in Section 4 that Takeuti-Adachi's scheme using MOWSLS can be interpreted as a "homogeneous version" of Shamir's $(t, n)$-threshold secret sharing with $t=2$, and mention that the known protocols for converting shares of two secrets $x, x^{\prime}$ in Shamir's scheme into shares of $x+x^{\prime}$ and of $x x^{\prime}$ [4] is extended to the case of Takeuti-Adachi's scheme. We note that instantiations of Latin squares for the use in Takeuti-Adachi's scheme different from weighted-sum ones are searched by computer
experiments in [8]. It is a future research topic to establish similar share conversion protocols based on MOLS not of weighted-sum type.

## 2 Notations and Definitions

Throughout the letter, $v$ denotes a fixed integer with $v \geq 2$. Let $[i, j]:=\{i, i+1, \ldots, j\}$ for integers $i \leq j$. For $a, n \in \mathbb{Z}$ with $n \geq 1$, let $a \bmod n$ denote the remainder of $a$ modulo $n$, taken from the range $0 \leq a \bmod n \leq n-1$, which is also regarded as an element of $\mathbb{Z} / n \mathbb{Z}$.

Let $L=(L[x, y])_{x, y}$ be an $v \times v$ array of integers $L[x, y] \in[0, v-1]$, with row index $x$ and column index $y$ running over $[0, v-1]$. We say that $L$ is a Latin square (of size $v \times v$ ) if for each row and each column, the entries of $L$ are all different (or equivalently, every number in $[0, v-1]$ appears at least once).

Definition 2. We say that two Latin squares $L_{1}$ and $L_{2}$ are orthogonal, denoted here by $L_{1} \perp L_{2}$, if the $v^{2}$ pairs $\left(L_{1}[x, y], L_{2}[x, y]\right) \in[0, v-1]^{2}$ are all different (or equivalently, every pair from $[0, v-1]^{2}$ appears at least once).

The following definition and proposition (which is well-known; proved here for the sake of completeness) are for a famous and efficient construction of Latin squares.
Definition 3. For $a, b \in[0, v-1]$, we define an $v \times v$ array $L_{a, b}$, which we call weighted-sum array, by

$$
L_{a, b}[x, y]:=a \cdot x+b \cdot y \bmod v \text { for } x, y \in[0, v-1] .
$$

Proposition 4. A weighted-sum array $L_{a, b}$ is a Latin square if and only if $\operatorname{gcd}(a, v)=1$ and $\operatorname{gcd}(b, v)=1$. When this is satisfied, we call the $L_{a, b}$ weighted-sum Latin square.
Proof. This follows by observing that for each $c \in\{a, b\}$, the values $c \cdot z \bmod v$ for $z \in[0, v-1]$ are all different if and only if $c \in(\mathbb{Z} / v \mathbb{Z})^{\times}$, i.e., $\operatorname{gcd}(c, v)=1$.

Due to this property, in what follows we focus on the case where $\operatorname{gcd}(a, v)=1$ and $\operatorname{gcd}(b, v)=1$.
We also consider the following kind of Latin squares. Here $L^{\mathrm{T}}$ denotes the transpose of a Latin square $L$, i.e., $L^{\mathrm{T}}[x, y]=L[y, x]$. Note that $\left(L_{a, b}\right)^{\mathrm{T}}=L_{b, a}$.
Definition 5. We say that a Latin square $L$ is self-transpose-orthogonal if $L \perp L^{\mathrm{T}}$.

## 3 On Upper Bounds for Mutually Orthogonal Sets

A sequence of Latin squares $L_{1}, \ldots, L_{\ell}$ satisfying that $L_{i} \perp L_{j}$ for any $i \neq j$ is called mutually orthogonal Latin squares (MOLS). We abbreviate mutually orthogonal weighted-sum Latin squares (i.e., every $L_{i}$ is a weighted-sum Latin square) as MOWSLS. We discuss about the maximum values of $\ell$ for MOLS and MOWSLS, denoted by $M(v)$ and $M^{\mathrm{WS}}(v)$.

### 3.1 The Case of Weighted-Sum Latin Squares

Let $P=P(v)$ denote the set of all prime factors of $v$. Then the condition stated in Proposition 4 is equivalent to that $\operatorname{gcd}(a, p)=1$ and $\operatorname{gcd}(b, p)=1$ for every $p \in P(v)$.

For a weighted-sum Latin square $L=L_{a, b}$, we define

$$
\lambda[p]=\lambda_{L}[p]=\lambda_{a, b}[p]:=\frac{b}{a} \bmod p \in\left(\mathbb{F}_{p}\right)^{\times}
$$

for any $p \in P(v)$, and define

$$
\lambda=\lambda_{L}=\lambda_{a, b}:=\left(\lambda_{a, b}[p]\right)_{p \in P(v)} .
$$

Note that for any tuple $\eta=\left(\eta_{p}\right)_{p \in P(v)} \in \prod_{p \in P(v)}\left(\mathbb{F}_{p}\right)^{\times}$, there is a weighted-sum Latin square $L$ with $\lambda_{L}=\eta$; take an integer $b \in[0, v-1]$ satisfying $\eta_{p}=b \bmod p$ for every $p \in P(v)$ by using Chinese Remainder Theorem (note that now $\operatorname{gcd}(b, v)=1$ ) and set $a:=1$. The following is the key property to prove our main result:

Theorem 6. For two weighted-sum Latin squares $L_{1}=L_{a_{1}, b_{1}}$ and $L_{2}=L_{a_{2}, b_{2}}$, we have $L_{1} \perp L_{2}$ if and only if $\lambda_{L_{1}}[p] \neq \lambda_{L_{2}}[p]$ for every $p \in P(v)$.

Proof. First, we suppose that the latter condition does not hold, i.e., $\lambda_{L_{1}}[p]=\lambda_{L_{2}}[p]$ for some $p \in P(v)$, and show that $L_{1} \not \perp L_{2}$. Fix an integer $\eta \in[0, v-1]$ with $\lambda_{L_{1}}[p]=\lambda_{L_{2}}[p]=\eta \bmod p$. Then for each $\mu \in\{1,2\}$, we have

$$
\eta \cdot a_{\mu} \equiv b_{\mu} \quad(\bmod p)
$$

therefore, by putting $v^{\prime}:=v / p \in \mathbb{Z}$, we have

$$
\eta v^{\prime} \cdot a_{\mu} \equiv v^{\prime} \cdot b_{\mu} \quad(\bmod v)
$$

Note that $1 \leq v^{\prime} \leq v-1$. Now we have

$$
L_{\mu}\left[0, v^{\prime}\right]-L_{\mu}\left[\eta v^{\prime} \bmod v, 0\right] \equiv v^{\prime} \cdot b_{\mu}-\eta v^{\prime} \cdot a_{\mu} \equiv 0 \quad(\bmod v),
$$

therefore

$$
\left(L_{1}\left[0, v^{\prime}\right], L_{2}\left[0, v^{\prime}\right]\right)=\left(L_{1}\left[\eta v^{\prime} \bmod v, 0\right], L_{2}\left[\eta v^{\prime} \bmod v, 0\right]\right) .
$$

This implies that $L_{1} \not \perp L_{2}$, as desired.
Now the remaining task is to show that the latter condition in the statement is not satisfied if $L_{1} \not \perp$ $L_{2}$. By the assumption, we have $\left(L_{1}[x, y], L_{2}[x, y]\right)=\left(L_{1}[u, w], L_{2}[u, w]\right)$ for some different pair of indices $(x, y) \neq(u, w)$. Then for each $\mu \in\{1,2\}$, we have

$$
a_{\mu} \cdot x+b_{\mu} \cdot y \equiv a_{\mu} \cdot u+b_{\mu} \cdot w \quad(\bmod v)
$$

Put $\Delta_{a}:=x-u$ and $\Delta_{b}:=w-y$, which are independent of $\mu$. Then we have

$$
\begin{equation*}
a_{\mu} \cdot \Delta_{a} \equiv b_{\mu} \cdot \Delta_{b} \quad(\bmod v) \tag{1}
\end{equation*}
$$

This and the property $\operatorname{gcd}\left(a_{\mu}, v\right)=\operatorname{gcd}\left(b_{\mu}, v\right)=1$ imply

$$
d:=\operatorname{gcd}\left(\Delta_{a}, v\right)=\operatorname{gcd}\left(a_{\mu} \cdot \Delta_{a}, v\right)=\operatorname{gcd}\left(b_{\mu} \cdot \Delta_{b}, v\right)=\operatorname{gcd}\left(\Delta_{b}, v\right)
$$

which is also independent of $\mu$. Put $\Delta_{a}^{\prime}:=\Delta_{a} / d \in \mathbb{Z}$ and $\Delta_{b}^{\prime}:=\Delta_{b} / d \in \mathbb{Z}$. Then both $\Delta_{a}^{\prime}$ and $\Delta_{b}^{\prime}$ are coprime to $v^{\prime}:=v / d$. Now by Eq.(1), we have

$$
a_{\mu} \cdot \Delta_{a}^{\prime} \equiv b_{\mu} \cdot \Delta_{b}^{\prime} \quad\left(\bmod v^{\prime}\right)
$$

therefore (by noticing that both $\Delta_{b}^{\prime}$ and $a_{\mu}$ are invertible modulo $v^{\prime}$ ) we have

$$
\frac{b_{\mu}}{a_{\mu}} \equiv \frac{\Delta_{a}^{\prime}}{\Delta_{b}^{\prime}} \quad\left(\bmod v^{\prime}\right)
$$

The right-hand side is independent of $\mu$, therefore we have

$$
\frac{b_{1}}{a_{1}} \equiv \frac{b_{2}}{a_{2}} \quad\left(\bmod v^{\prime}\right)
$$

Moreover, the assumption $(x, y) \neq(u, w)$ implies that at least one of $\Delta_{a}$ and $\Delta_{b}$ is not a multiple of $v$, therefore we have $d<v$. This implies that $v^{\prime}>1$, and by taking any prime factor $p$ of $v^{\prime}$, we have $p \in P(v)$ and

$$
\frac{b_{1}}{a_{1}} \equiv \frac{b_{2}}{a_{2}} \quad(\bmod p)
$$

i.e., $\lambda_{L_{1}}[p]=\lambda_{L_{2}}[p]$. Hence the latter condition in the statement does not hold, as desired.

By Theorem 6, members of any MOWSLS must have different values of $\lambda\left[p_{0}\right] \in\left(\mathbb{F}_{p_{0}}\right)^{\times}$where $p_{0}:=$ $\min P(v)$, therefore $M^{\mathrm{WS}}(v) \leq\left|\left(\mathbb{F}_{p_{0}}\right)^{\times}\right|=p_{0}-1$; while $L_{1, b}$ for $b \in\left[1, p_{0}-1\right]$ form MOWSLS with cardinality $p_{0}-1$. This proves Theorem 1 in the introduction.

Theorem 6 also yields the following corollary:
Corollary 7. Let $L=L_{a, b}$ be a weighted-sum Latin square. Then all the following conditions are equivalent:

1. L is self-transpose-orthogonal.
2. $\lambda_{L}[p] \neq \pm 1$ in $\mathbb{F}_{p}$ for every $p \in P(v)$.
3. $\operatorname{gcd}(a+b, v)=1$ and $\operatorname{gcd}(a-b, v)=1$.

Proof. By Theorem 6, we have $L_{a, b} \perp L_{b, a}$ if and only if $\lambda_{L}[p] \neq \lambda_{L}[p]^{-1}$, i.e., $\lambda_{L}[p] \neq \pm 1$ in $\mathbb{F}_{p}$, for every $p \in P(v)$. This is also equivalent to that $b^{2} \not \equiv a^{2}(\bmod p)$, i.e., $a^{2}-b^{2}=(a+b)(a-b) \not \equiv 0(\bmod p)$, for every $p \in P(v)$. The last condition means that $\operatorname{gcd}(a \pm b, p)=1$ for every $p \in P(v)$, which is equivalent to $\operatorname{gcd}(a \pm b, v)=1$.

By this result, when we restrict MOWSLS further to self-transpose-orthogonal ones, two values $\pm 1$ are excluded from the values of $\lambda[p]$, therefore the maximum cardinality decreases to $p_{0}-3$ (such a set does not exist when $p_{0} \leq 3$ ).

### 3.2 The General Case

Takeuti and Adachi [10] proposed the following construction of a (perfectly secure) ( $t, n$ )-threshold secret sharing $\left((t, n)\right.$-SS, in short) scheme with parameter $t=2$, which uses $n-1$ MOLS $L_{1}, \ldots, L_{n-1}$ of size $v \times v$ as public parameters:
Share Generation Given a secret $x \in[0, v-1]$ to be shared, the algorithm chooses $y \in[0, v-1]$ uniformly at random, and computes $z_{i}:=L_{i}[x, y]$ for each $i \in[1, n-1]$. Then $z_{i}$ is the share of $x$ for party $P_{i}$, and $y$ is the share of $x$ for party $P_{n}$.

Secret Reconstruction When a pair of shares $z_{i}$ and $y$ from parties $P_{i}(i \neq n)$ and $P_{n}$ is given, the algorithm outputs the unique index $x^{\prime}$ with $L_{i}\left[x^{\prime}, y\right]=z_{i}$. When a pair of shares $z_{i}$ and $z_{j}$ from parties $P_{i}$ and $P_{j}(i, j \neq n)$ is given, the algorithm determines the unique pair of indices $\left(x^{\prime}, y^{\prime}\right)$ with $\left(L_{i}\left[x^{\prime}, y^{\prime}\right], L_{j}\left[x^{\prime}, y^{\prime}\right]\right)=\left(z_{i}, z_{j}\right)$ and outputs $x^{\prime}$.
On the other hand, the following lower bound for the size of share spaces of $(t, n)$-SS schemes is known (it is known as an unpublished work by J. Kilian and N. Nisan, 1990; see e.g., the fourth paragraph of Section 1.2.3 of [3]):

Proposition 8. For $i \in[1, n]$, let $\mathcal{S}_{i}$ be the set of possible shares for $i$-th party in a $(t, n)$-SS scheme with $2 \leq t \leq n-1$. Then $\sum_{i=1}^{n} \log _{2}\left|\mathcal{S}_{i}\right| / n \geq \log _{2}(n-t+2)$.

By applying Proposition 8 to Takeuti-Adachi's $(2, n)$-SS scheme where $\mathcal{S}_{i}=[0, v-1]$, it follows that $\log _{2} v \geq \log _{2} n$, i.e., $v \geq n$. Then, any MOLS of cardinality $M(v)$ gives a $(2, n)$-SS scheme with $n=M(v)+1$ and therefore satisfies that $M(v)+1 \leq v$. This yields a known upper bound $M(v) \leq v-1$ mentioned in the introduction.

## 4 Relation to Secure Multiparty Computation

In the research area of secure multiparty computation (MPC) in cryptography, several methods of computing shares of the addition/multiplication of two secrets from given shares of each secret in various secret sharing schemes have been proposed in the literature, e.g., [1, 2, 4]. Here we describe such a method for TakeutiAdachi's $(2, n)$-SS scheme in Section 3.2 with $n \geq 3$ when using MOWSLS where $v$ is a prime and the set $[0, v-1]$ is identified with $\mathbb{F}_{v}=\mathbb{Z} / v \mathbb{Z}$. Then we explain a relation to Shamir's secret sharing [9].

Let $\left(z_{1}, \ldots, z_{n-1}, y\right)$ and $\left(z_{1}^{\prime}, \ldots, z_{n-1}^{\prime}, y^{\prime}\right)$ be tuples of shares of secrets $x$ and $x^{\prime}$, respectively.

### 4.1 Computing the Addition

By the construction of shares, we have

$$
\begin{equation*}
z_{i}=a_{i} \cdot x+b_{i} \cdot y \text { and } z_{i}^{\prime}=a_{i} \cdot x^{\prime}+b_{i} \cdot y^{\prime} \tag{2}
\end{equation*}
$$

for each $i \in[1, n-1]$ (where the equalities are considered in $\mathbb{F}_{v}$ ). Therefore we have

$$
z_{i}+z_{i}^{\prime}=a_{i} \cdot\left(x+x^{\prime}\right)+b_{i} \cdot\left(y+y^{\prime}\right) .
$$

This means that $\left(z_{1}+z_{1}^{\prime}, \ldots, z_{n-1}+z_{n-1}^{\prime}, y+y^{\prime}\right)$, which can be obtained by local addition of each party's shares, forms a tuple of shares for secret $x+x^{\prime}$.

### 4.2 Computing the Multiplication

First, for any $i \in[1, n-1]$, from Eq.(2), we have

$$
\begin{equation*}
z_{i} z_{i}^{\prime}=a_{i}^{2} \cdot x x^{\prime}+a_{i} b_{i} \cdot\left(x y^{\prime}+x^{\prime} y\right)+b_{i}^{2} \cdot y y^{\prime} \tag{3}
\end{equation*}
$$

Note that the same relation also holds for $i=n$ when we put $z_{n}:=y, z_{n}^{\prime}:=y^{\prime}, a_{n}:=0$, and $b_{n}:=1$.
Lemma 9. In the setting above, for any three distinct indices $i, j, k \in\{1, \ldots, n\}$, we have

$$
\left(\begin{array}{ccc}
a_{i}{ }^{2} & a_{j}{ }^{2} & a_{k}{ }^{2}  \tag{4}\\
a_{i} b_{i} & a_{j} b_{j} & a_{k} b_{k} \\
b_{i}{ }^{2} & b_{j}{ }^{2} & b_{k}{ }^{2}
\end{array}\right)\left(\begin{array}{c}
C_{i ; j, k} \\
C_{j ; k, i} \\
C_{k ; i, j}
\end{array}\right)=\left(\begin{array}{l}
1 \\
0 \\
0
\end{array}\right),
$$

where, for distinct indices $\alpha, \beta, \gamma \in[1, n]$,

$$
\begin{equation*}
C_{\alpha ; \beta, \gamma}:=\frac{b_{\beta} b_{\gamma}}{\left(a_{\alpha} b_{\beta}-a_{\beta} b_{\alpha}\right)\left(a_{\alpha} b_{\gamma}-a_{\gamma} b_{\alpha}\right)} \in \mathbb{F}_{v} \tag{5}
\end{equation*}
$$

Proof. Let $A$ denote the $3 \times 3$ matrix in Eq.(4). By dividing each column of $A$ by $b_{i}{ }^{2}, b_{j}{ }^{2}$, and $b_{k}{ }^{2}$, respectively, we obtain a Vandermonde-type matrix

$$
\left(\begin{array}{ccc}
\left(a_{i} / b_{i}\right)^{2} & \left(a_{j} / b_{j}\right)^{2} & \left(a_{k} / b_{k}\right)^{2} \\
a_{i} / b_{i} & a_{j} / b_{j} & a_{k} / b_{k} \\
1 & 1 & 1
\end{array}\right) .
$$

Therefore we have

$$
\frac{\operatorname{det}(A)}{b_{i}^{2} b_{j}^{2} b_{k}^{2}}=\left(\frac{a_{i}}{b_{i}}-\frac{a_{j}}{b_{j}}\right)\left(\frac{a_{i}}{b_{i}}-\frac{a_{k}}{b_{k}}\right)\left(\frac{a_{j}}{b_{j}}-\frac{a_{k}}{b_{k}}\right)
$$

which is non-zero by the orthogonality of Latin squares and Theorem 6. Hence

$$
\operatorname{det}(A)=\left(a_{i} b_{j}-a_{j} b_{i}\right)\left(a_{i} b_{k}-a_{k} b_{i}\right)\left(a_{j} b_{k}-a_{k} b_{j}\right) .
$$

Now Cramer's rule to solve the system of linear equations (4) yields the values of $C_{i ; j, k}, C_{j ; k, i}$, and $C_{k ; i, j}$ as follows:

$$
\begin{aligned}
& C_{i ; j, k}=\operatorname{det}(A)^{-1} \operatorname{det}\left(\begin{array}{cc}
a_{j} b_{j} & a_{k} b_{k} \\
b_{j}{ }^{2} & b_{k}{ }^{2}
\end{array}\right)=\operatorname{det}(A)^{-1} b_{j} b_{k}\left(a_{j} b_{k}-a_{k} b_{j}\right), \\
& C_{j ; k, i}=-\operatorname{det}(A)^{-1} \operatorname{det}\left(\begin{array}{cc}
a_{i} b_{i} & a_{k} b_{k} \\
b_{i}{ }^{2} & b_{k}{ }^{2}
\end{array}\right)=-\operatorname{det}(A)^{-1} b_{k} b_{i}\left(a_{i} b_{k}-a_{k} b_{i}\right), \\
& C_{k ; i, j}=\operatorname{det}(A)^{-1} \operatorname{det}\left(\begin{array}{cc}
a_{i} b_{i} & a_{j} b_{j} \\
b_{i}{ }^{2} & b_{j}{ }^{2}
\end{array}\right)=\operatorname{det}(A)^{-1} b_{i} b_{j}\left(a_{i} b_{j}-a_{j} b_{i}\right) .
\end{aligned}
$$

They are equal to the values as in Eq.(5).

Now we obtain the following protocol for multiplication of shared secrets, where $i_{0}, i_{1}, i_{2} \in[1, n]$ are any three distinct and publicly known indices:

1. For each $\mu \in\{0,1,2\}$, party $P_{i_{\mu}}$ sets $(\alpha, \beta, \gamma):=\left(i_{\mu}, i_{\mu+1 \bmod 3}, i_{\mu+2 \bmod 3}\right)$, and computes

$$
X_{\mu}:= \begin{cases}C_{\alpha ; \beta, \gamma} \cdot z_{i_{\mu}} z_{i_{\mu}}^{\prime} & \text { if } i_{\mu} \neq n \\ C_{\alpha ; \beta, \gamma} \cdot y y^{\prime} & \text { if } i_{\mu}=n\end{cases}
$$

where the coefficient $C_{\alpha ; \beta, \gamma}$ is as defined in Lemma 9 (with $a_{n}:=0$ and $b_{n}:=1$ ). Then $P_{i_{\mu}}$ generates shares $Z_{1}^{\langle\mu\rangle}, \ldots, Z_{n-1}^{\langle\mu\rangle}, Y^{\langle\mu\rangle}$ of $X_{\mu}$ (by the same ( $2, n$ )-SS scheme), and sends $Z_{\ell}^{\langle\mu\rangle}$ to party $P_{k}$ for $k \in[1, n-1]$ and $Y^{\langle\mu\rangle}$ to party $P_{n}$.
2. Each party generates a new share by adding the three shares received in the previous step.

By Eq.(3) and the additive property of the shares explained in Section 4.1, the new share generated by the protocol is (by putting $z_{n}:=y$ and $z_{n}^{\prime}:=y^{\prime}$ as above) a share of

$$
\begin{aligned}
X_{0}+X_{1}+X_{2} & =\left(\begin{array}{lll}
x x^{\prime} & x y^{\prime}+x^{\prime} y & y y^{\prime}
\end{array}\right)\left(\begin{array}{ccc}
a_{i_{0}}{ }^{2} & a_{i_{1}}{ }^{2} & a_{i_{2}}{ }^{2} \\
a_{i_{0}} b_{i_{0}} & a_{i_{1}} b_{i_{1}} & a_{i_{2}} b_{i_{2}} \\
b_{i_{0}}{ }^{2} & b_{i_{1}}{ }^{2} & b_{i_{2}}{ }^{2}
\end{array}\right)\left(\begin{array}{l}
C_{i_{0} ; i_{1}, i_{2}} \\
C_{i_{1} ; i_{2}, i_{0}} \\
C_{i_{2} ; i_{0}, i_{1}}
\end{array}\right) \\
& =\left(\begin{array}{lll}
x x^{\prime} & x y^{\prime}+x^{\prime} y & y y^{\prime}
\end{array}\right)\left(\begin{array}{l}
1 \\
0 \\
0
\end{array}\right)=x x^{\prime}
\end{aligned}
$$

as desired, where we used Lemma 9 at the second equality.

### 4.3 Relation to Shamir's Secret Sharing

In the case where $a_{1}=\cdots=a_{n-1}=1$, given a secret $x$ and party $P_{n}$ 's share $y$ of $x$, we consider a polynomial $f(T):=y T+x \in \mathbb{F}_{v}[T]$ of degree at most one. Then the share $z_{i}$ of $x$ for party $P_{i}(i \neq n)$ is given by

$$
z_{i}=a_{i} \cdot x+b_{i} \cdot y=y \cdot b_{i}+x=f\left(b_{i}\right)
$$

and the share for party $P_{n}$ is the coefficient $y$ of $f(T)$ at the highest degree, while the secret is $x=f(0)$. This is the same situation as "the point at infinity" variant of Shamir's ( $2, n$ )-SS scheme described in Section 11.7 of [6]. On the other hand, for general $a_{1}, \ldots, a_{n-1}$, by taking homogenization $f\left(T_{1}, T_{0}\right)=y T_{1}+x T_{0}$ of $f(T), P_{i}$ 's share $z_{i}(i \neq n)$ is equal to $a_{i} \cdot x+b_{i} \cdot y=f\left(b_{i}, a_{i}\right)$ (corresponding to a non-infinity point $\left[b_{i}: a_{i}\right]$ in the projective line $\mathbb{P}_{1}\left(\mathbb{F}_{v}\right)$ ), and $P_{n}$ 's share $y$ is also equal to $F(1,0)$ (corresponding to the point at infinity $\left.[1: 0] \in \mathbb{P}_{1}\left(\mathbb{F}_{v}\right)\right)$. Hence Takeuti-Adachi's $(2, n)$-SS scheme using MOWSLS and the protocols in Sections 4.1 and 4.2 can be seen as a "homogeneous version" of Shamir's scheme and the corresponding MPC protocols [4].
