Abstract. The lattice-based post-quantum cryptosystem NTRU is used by Google for protecting Google's internal communication. In NTRU, polynomial multiplication is one of bottleneck. In this paper, we explore the interactions between polynomial multiplications, Toeplitz matrixvector products, and vectorization with architectural insights. For a unital commutative ring R, a positive integer n, and an element  $\zeta \in R$ , we reveal the benefit of vector-by-scalar multiplication instructions while multiplying in  $R[x]/\langle x^n - \zeta \rangle$ .

We aim at designing an algorithm exploiting no algebraic and numbertheoretic properties of n and  $\zeta$ . An obvious way is to multiply in R[x]and reduce modulo  $x^n - \zeta$ . Since the product in R[x] is a polynomial of degree at most 2n - 2, one usually chooses a polynomial modulus gsuch that (i) deg $(g) \geq 2n - 1$ , and (ii) there exists a well-studied fast polynomial multiplication algorithm f for multiplying in  $R[x]/\langle g \rangle$ .

We deviate from common approaches and point out a novel insight with dual modules and vector-by-scalar multiplications. Conceptually, we relate the module-theoretic duals of  $R[x]/\langle x^n - \zeta \rangle$  and  $R[x]/\langle g \rangle$  with Toeplitz matrix-vector products, and demonstrate the benefit of Toeplitz matrix-vector products with vector-by-scalar multiplication instructions. It greatly reduces the register pressure, and allows us to multiply with essentially no permutation instructions that are commonly used in vectorized implementation.

We implement the ideas for the NTRU parameter sets ntruhps2048677 and ntruhrss701 on a Cortex-A72 implementing the Armv8.0-A architecture with the single-instruction-multiple-data (SIMD) technology Neon. For polynomial multiplications, our implementation is 2.18× and 2.23× for ntruhps2048677 and ntruhrsss701 than the state-of-the-art optimized implementation. We also vectorize the polynomial inversions and sorting network by employing existing techniques and translating AVX2-optimized implementation, our key generation, encapsulation, and decapsulation for ntruhps2048677 are 7.67×, 2.48×, and 1.77× faster, respectively. For ntruhrss701, our key generation, encapsulation, and decapsulation are 7.99×, 1.47×, and 1.56× faster, respectively.

## 1 Introduction

At PQCrypto 2016, the National Institute of Standards and Technology (NIST) announced the Post-Quantum Cryptography (PQC) Standardization Process for replacing existing standards for public-key cryptography with quantum-resistant cryptosystems. For lattice-based cryptosystems, polynomial multiplications had been the most time-consuming operations. In this paper, we investigate the interations between the underlying mathematical structure of polynomial rings and the architectural insights of vector-by-scalar multiplication instructions in instruction set architectures (ISAs).

In the NTRU submission [6] to the NIST PQC Standardization, polynomial rings of the form  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$  and  $\mathbb{Z}_q[x]/\langle \sum_{i=0}^{n-1} x^i \rangle$  are used where  $\mathbb{Z}_q$  is an integer ring, and n is a prime. Since  $x^n - 1 = (x-1)\sum_{i=0}^{n-1} x^i$ , multiplications in  $\mathbb{Z}_q[x]/\langle \sum_{i=0}^{n-1} x^i \rangle$  is often implemented as  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$  followed by reduction modulo  $\sum_{i=0}^{n-1} x^i$ . In this paper, we focus on the polynomial multiplications in  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$ .

Common approaches for multiplying two size-*n* polynomials in  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$ usually multiply in  $\mathbb{Z}_q[x]$  and reduce modulo  $x^n - 1$ . Let  $\boldsymbol{a}, \boldsymbol{b}$  be polynomials in  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$  and f be an algebra monomorphism computing  $\boldsymbol{ab} = f^{-1}(f(\boldsymbol{a})f(\boldsymbol{b}))$  in  $\mathbb{Z}_q[x]$ . Recent work [13] showed that the module-theoretic dual  $f(\boldsymbol{a})^*$  can be used for multiplying a Toeplitz matrix and a vector. Since polynomial multiplications in  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$  can be regarded as a Toeplitz matrixvector multiplication, we don't need the reduction modulo  $x^n - 1$  anymore.

In this paper, we point out the architectural benefit of Toeplitz matrix-vector products for ISAs implementing vector-by-scalar multiplication instructions. We show that the outer-product approach multiplying two matrices in cubic time implies efficient Toeplitz matrix-vector products with vector-by-scalar multiplication instructions.

## 1.1 Contributions

We summarize our contributions as follows.

- We point out the architectural benefit of Toeplitz matrix-vector products for vectorization and implement the ideas on a Cortex-A72 implementing Armv8.0-A where vector-by-scalar multiplication instructions are supported.
- We explain that Toeplitz matrix-vector product is actually a generic approach it is only tied to the shape of polynomial rings and not the underlying monomorphism. Prior work [13] doesn't seem to observe this and they compared the Toeplitz matrix-vector product with Toom–Cook and the plain polynomial multiplication with number-theoretic transform<sup>4</sup> followed by reduction modulo  $x^n 1$ .

<sup>&</sup>lt;sup>4</sup> Number-theoretic transform refers to a broad family of algebra monomorphisms that doesn't contain Toom–Cook.

- For the performance of polynomial multiplications, we outperform the stateof-the-art optimized implementation by  $2.18 \times$  and  $2.23 \times$  for the NTRU parameter sets ntruhps2048677 and ntruhrss701, respectively.
- For the overall performance of the scheme, our ntruhps2048677 key generation, encapsulation, and decapsulation is  $7.67 \times$ ,  $2.48 \times$ , and  $1.77 \times$  faster than the state-of-the-art optimized implementation; our ntruhrss701 key generation, encapsulation, and decapsulation is  $7.99 \times$ ,  $1.47 \times$ , and  $1.56 \times$ faster than the state-of-the-art optimized implementation.

## 1.2 Code.

Our source code is publicly available at

https://github.com/vector-polymul-ntru-ntrup/NTRU.

#### 1.3 Structure of this Paper.

This paper is structured as follows: Section 2 describes our target operations and platforms. Section 3 surveys polynomial transformations used for multiplications. Section 4 goes through the benefit of Toeplizt matrix–vector products. Section 5 describes our implementations. We show the performance numbers in Section 6.

## 2 Preliminaries

Sections 2.1 describe the polynomials rings in NTRU, and Section 2.2 describes our target platform Cortex-A72.

## 2.1 Polynomials in NTRU

The NTRU submission comprises two families NTRU-HPS and NTRU-HRSS. Both operate on polynomial rings  $\mathbb{Z}_3[x]/\langle \Phi_n \rangle$ ,  $\mathbb{Z}_q[x]/\langle \Phi_n \rangle$ , and  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$ where q is a power of 2, n is a prime, and  $\Phi_n$  is the nth cyclotomic polynomial, which for prime n is  $\frac{x^n-1}{x-1} = \sum_{i < n} x^i$ . We target the parameter sets ntruhps2048677 ((q, n) = (2048, 677)) and ntruhrss701 ((q, n) = 8192, 701). For more parameter sets and details, we refer to the specification [6]. While NTRU also requires inversions in  $\mathbb{Z}_3[x]/\langle \Phi_n \rangle$  and  $\mathbb{Z}_q[x]/\langle x^n - 1 \rangle$ , we focus on multiplying polynomials in  $\mathbb{Z}_{2048}[x]/\langle x^{677} - 1 \rangle$  and  $\mathbb{Z}_{8192}[x]/\langle x^{701} - 1 \rangle$ .

## 2.2 Cortex-A72

Our target platform is the ARM Cortex-A72. Cortex-A72 implements the 64-bit Armv8.0-A instruction set architecture. It is a superscalar Central Processing Unit (CPU) with an in-order frontend and an out-of-order backend. We summarize some architectural features relevant to this paper, and refer to [1] for more details about the pipelines.

Han-Ting Chen, Yi-Hua Chung, Vincent Hwang, and Bo-Yin Yang

SIMD Registers. In Armv8.0-A, there are 32 architectural 128-bit SIMD registers each viewable as packed 8-, 16-, 32-, or 64-bit elements. The width of the element is specified the suffices .16B .8H, .4S, and .2D respectively on the register name. For referencing a certain lane, we use the annotation .H[5] for the 5th (zero-based) halfword of the register and similarly for other lanes and data widths [2, Figure A1-1].

Armv8-A Vector Instructions. A plain mul multiplies corresponding vector elements and returns same-sized results. Additionally, mul also refers to another instruction encoding — vector-by-scalar multiplication — if the last operand is a lane of a register. In this case mul multiplies the vector by a scalar (the lane value). This simple feature plays significant roles on maximizing register utilization and minimizing permutations. There are many variants of multiplications: mla/mls computes the same product vector and accumulates to or subtracts from the destination. Next, the shifts: shl shifts left; sshr arithmetically shifts right. For basic arithmetic, the usual add/sub adds/subtracts the corresponding elements. Then we have permutations — uzp{1,2} extracts the even and odd positions respectively from a pair of vectors and concatenates the results into a vector. zip{1,2} takes the bottom and top halves of a pair of vectors and riffle-shuffles them into the destination.

## **3** Polynomial Multiplications

4

This section surveys the Chinese remainder theorem for polynomial rings and Toom–Cook, and is structured as follows. We assume all the rings are commutative and unital in this paper. Section 3.1 reviews the Chinese remainder theorem for polynomial rings. This forms the basis of various fast polynomial ring transformations. Section 3.2 reviews Toom–Cook. Section 3.3 reviews the bit losses of Toom–Cook.

## 3.1 The Chinese Remainder Theorem for Polynomial Rings

Let  $n = \prod_l n_l$  and  $g_{i_0,\dots,i_{h-1}} \in R[x]$  be coprime polynomials for  $i_l \in [0, n_l)$ . The CRT gives us the following the isomorphism

$$\prod_{i_0,\dots,i_{l-1}} \frac{R[x]}{\left\langle \prod_{i_l,\dots,i_{h-1}} \boldsymbol{g}_{i_0,\dots,i_{h-1}} \right\rangle} \cong \prod_{i_0,\dots,i_l} \frac{R[x]}{\left\langle \prod_{i_{l+1},\dots,i_{h-1}} \boldsymbol{g}_{i_0,\dots,i_{h-1}} \right\rangle}$$

for all  $l = 1, ..., h-1^5$ . We call each of the isomorphism "a layer of computation" and "a layer" for short. Usually, multiplications in  $\prod_{i_0,...,i_{h-1}} R[x] / \langle g_{i_0,...,i_{h-1}} \rangle$ 

<sup>&</sup>lt;sup>5</sup> For possibly non-commutative unital rings, we only have  $R[x]/\langle g_i \rangle \cap \langle g_j \rangle \cong R[x]/\langle g_i \rangle \times R[x]/\langle g_j \rangle$  for coprime polynomials  $g_i$  and  $g_j$ . If R is commutative, R[x] is also commutative and we have  $\langle g_i \rangle \cap \langle g_j \rangle = \langle g_i \rangle \langle g_j \rangle = \langle g_i g_j \rangle$ . This leads to  $R[x]/\langle g_i g_j \rangle \cong R[x]/\langle g_i \rangle \times R[x]/\langle g_j \rangle$  in our context.

are cheap. If all the layers are cheap, we have an algorithmic improvement for multiplying polynomials in  $R[x]/\langle \prod_{i_0,\ldots,i_{h-1}} \boldsymbol{g}_{i_0,\ldots,i_{h-1}} \rangle$ . If the  $n_l$  is a small constant, then it is usually cheap to decompose a polynomial ring into a product of  $n_l$  polynomial rings.

#### 3.2 Toom–Cook (TC) and Karatsuba

For a positive integer n, we define  $R[x]_{<n}$  as  $\{a(x) \in R[x] | \deg(a(x)) < n\}$ , the set of polynomials with degree less than n. Toom–Cook [7,17] and Karatsuba [11] are divide-and-conquer approaches for multiplying polynomials in R[x]. We can also use them for multiplying polynomials in  $R[x]_{<n}$ . We introduce  $y \sim x^{\frac{n}{k}}$  (zero-pad so that k|n) [4], and map  $R[x]_{<n} \hookrightarrow R[x]/\langle x^{\frac{n}{k}} - y \rangle [y]_{<k} \hookrightarrow R'[y]_{<k}$  for  $R' = R[x]/\langle g \rangle$  with deg  $g \geq \frac{2n}{k} - 1$ . For  $a, b \in R'[y]_{<k}$ , a k-way Toom–Cook computes  $ab \in R'[y]_{<2k-1}$  via

For  $\boldsymbol{a}, \boldsymbol{b} \in R'[y]_{<k}$ , a k-way Toom–Cook computes  $\boldsymbol{ab} \in R'[y]_{<2k-1}$  via evaluating  $\boldsymbol{a}, \boldsymbol{b}$  at suitably chosen  $s_i$ 's in R'. In other words, we apply the map  $R'[y]_{<k} \hookrightarrow R'[y] / \langle \prod_{i=0}^{2k-2} (y-s_i) \rangle \cong \prod_{i=0}^{2k-2} R'[y] / \langle y-s_i \rangle$ . If one of the evaluation points is  $s_i = \infty$ , the corresponding map into

If one of the evaluation points is  $s_i = \infty$ , the corresponding map into  $R'[y]/\langle y - s_i \rangle$  takes the highest degree coefficient (deg-(k - 1) for a, b, deg-(2k - 2) for ab). [11] chose k = 2 at  $\{s_i\}_i = \{0, 1, \infty\}$ ; [17] chose  $\{s_i\}_i = \{0, \pm 1, \ldots, \pm (k - 1)\}$ ; and [18, Page 31] replaced -k + 1 with  $\infty$ . We write  $\mathbf{TC}_{(2k-1)\times k}$  for the matrix mapping the coefficients of a deg < k polynomial into  $\prod_{i=0}^{2k-2} R'[y]/\langle y - s_i \rangle$  and  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1}$  for the matrix mapping  $\prod_{i=0}^{2k-2} R'[y]/\langle y - s_i \rangle$  into  $R[y] / \langle \prod_{i=0}^{2k-2} (y - s_i) \rangle$ .

A key observation is that while working over  $\mathbb{Z}_{2^k}$  for k = 5 and  $\{s_i\} = \{0, \pm 1, \pm 2, \pm \frac{1}{2}, 3, \infty\}$ ,  $\mathbf{TC}_{9\times 9}^{-1}$  only requires "division by 8". This implies 3-bit losses. See Appendix A for an illustration.

## 3.3 Enlarging Coefficient Rings

We briefly explain how to divide a power of 2 when 2 is not invertible, for example while working over  $\mathbb{Z}_{2^k}$ . Suppose we want  $r \in \mathbb{Z}_{2^k}$ . We instead compute  $2^{\epsilon}r \in \mathbb{Z}_{2^{k+\epsilon}}$ , and right-shift  $2^{\epsilon}r$  by  $\epsilon$  bits [4, Section 7, Paragraph "What to do when 2 is not invertible"]. For our Toom–Cook defined over  $\mathbb{Z}_{2^k}$ , we would compute in  $\mathbb{Z}_{2^{16}}$  so  $r = \frac{2^{16-k}r}{2^{16-k}} \in \mathbb{Z}_{2^k}$  can be derived by right-shifting  $2^{16-k}r \in \mathbb{Z}_{2^{16}}$  by 16 - k bits.

## 4 Toeplitz Matrix–Vector Product

In this section, we go through the benefit of Toeplitz matrix–vector products. The fundamental of using Toeplitz matrix–vector product is best described via R-modules, dual R-modules, and associative R-algebra. When the context is clear, we call an R-module a module and an associative R-algebra an algebra.

Section 4.1 reviews some basics about modules and algebras. Section 4.2 distinguish the inner-product-based and outer-product-based approaches for matrix– vector product. Section 4.3 introduces Toeplitz matrix–vector product. Section 4.4 explains the benefit of vector-by-scalar multiplications. Section 4.5 presents the generic Toeplitz matrix–vector product conversion from ring monomorphisms computing the double-size products.

#### 4.1 Module and Associative Algebra

This section goes through some basics about modules, dual modules, and associative algebras. Readers familiar with these basic algebraic structures can skip this section.

Module and dual module. Let (M, +) be an abelian group and R a ring. We turn M into an R-module by introducing a scalar multiplication  $\cdot_M : R \times M \to M$  (we write  $r \cdot_M a$  for  $(\cdot_M)(r, a)$ ) satisfying the following:

- $\forall \boldsymbol{a}, \boldsymbol{b} \in M, \forall r, s \in R, (r+s) \cdot_M (\boldsymbol{a} + \boldsymbol{b}) = r \cdot_M \boldsymbol{a} + r \cdot_M \boldsymbol{b} + s \cdot_M \boldsymbol{a} + s \cdot_M \boldsymbol{b}.$  $- \forall \boldsymbol{a} \in M, 1 \cdot_M \boldsymbol{a} = \boldsymbol{a}.$
- $\forall \boldsymbol{a} \in M, \forall r, s \in R, (rs) \cdot_M \boldsymbol{a} = r \cdot_M (s \cdot_M \boldsymbol{a}).$

We call  $(M, +, \cdot_M)$  a left *R*-module. One can define a right *R*-module in a similar way by identifying a scalar multiplication from  $M \times R$  to M. Since we assume *R* is commutative, we do not distinguish between left and right *R*-modules and simply call them *R*-modules. For elements  $\mathbf{b}_0, \ldots, \mathbf{b}_{n-1} \in M$ , if they are linearly independent and every element in M can be expressed as a linear combination of  $\mathbf{b}_0, \ldots, \mathbf{b}_{n-1}$ , we call  $\{\mathbf{b}_0, \ldots, \mathbf{b}_{n-1}\}$  a basis of M and n the rank. A free module of rank n is a module with a basis of n elements and is very close to an ndimensional vector space in our context. We denote by  $R^n$  for the free module of rank n. Notice that a ring R and a polynomial ring  $R[x]/\langle g \rangle$  are free modules, and the matrix ring  $M_{n \times n}(R)$  is an R-module.

An *R*-module homomorphism is a map  $\eta: M \to N$  satisfying:

 $\forall r \in R, \forall \boldsymbol{a}, \boldsymbol{b} \in M, \eta(r \cdot_M \boldsymbol{a} + \boldsymbol{b}) = r \cdot_N \eta(\boldsymbol{a}) + \eta(\boldsymbol{b}).$ 

One can verify that the set of R-module homomorphisms  $\operatorname{Hom}_R(M, R)$  from M to R is an R-module. We call  $\operatorname{Hom}_R(M, R)$  the dual of M, and denote it as  $M^*$ . If M is a free R-module of finite rank, it is isomorphic to  $M^*$ . For an R-module homomorphism  $\eta : M \to N$ , we define the transpose of  $\eta$  as the R-module homomorphism  $\eta^* : N^* \to M^*$  sending  $\mathbf{a}^*$  to  $\mathbf{a}^* \circ \eta$ .

Associative algebra. For rings R and A, we turn A into an associative Ralgebra by introducing a module structure. One identifies the module addition
with the ring addition, and provide a scalar multiplication  $\cdot_{A} : R \times A \to A$  for
the module structure satisfying

$$\forall r \in R, \forall \boldsymbol{a}, \boldsymbol{b} \in \mathcal{A}, r \cdot_{\mathcal{A}} (\boldsymbol{a}\boldsymbol{b}) = (r \cdot_{\mathcal{A}} \boldsymbol{a})\boldsymbol{b} = \boldsymbol{a}(r \cdot_{\mathcal{A}} \boldsymbol{b}).$$

6

An *R*-algebra homomorphism is a map that is a ring homomorphism and a module homomorphism at the same time.

Obviously, a polynomial ring is an R-algebra and all the ring monomorphisms in Section 3 are also module monomorphisms; therefore, they are algebra monomorphisms.

## 4.2 Matrix–Vector Products

There are two basic ways to multiply a matrix by a vector. For a matrix M, we denote  $M[i_0][i_1]$  for the  $(i_0, i_1)$ -th entry,  $M[i_0][-]$  for the  $i_0$ -th row, and  $M[-][i_1]$  for the  $i_1$ -th column of M. Let A be an  $n_0 \times n_1$  matrix a B be a column vector of  $n_1$  elements. We wish to compute the matrix-vector product C = AB. Algorithm 1 computes the result with several inner products of the rows of the matrix and the vector. Algorithm 2 accumulates several products of the columns of the matrix and the corresponding elements of the vector.

Algorithm 1 Inner-product-based matrix-vector multiplication.

1: for  $i_0 = 0, ..., n_0 - 1$  do 2: for  $i_1 = 0, ..., n_1 - 1$  do 3:  $C[i_0] = C[i_0] + A[i_0][i_1]B[i_1]$ 4: end for 5:  $\triangleright$  Inner product of the vectors  $A[i_0][-]$  and B[-]. 6: end for

Algorithm 2 Outer-product-based matrix-vector multiplication.				
1: for $i_1 = 0, \ldots, n_1 - 1$ do				
2: <b>for</b> $i_0 = 0, \ldots, n_0 - 1$ <b>d</b>	do			
3: $C[i_0] = C[i_0] + A$	$[i_0] [i_1] B [i_1]$			
4: end for				
5:	$\triangleright$ Outer product of the vectors $A[-][i_1]$ and $B[i_1]$ .			
6: end for	-			

In the context of a vector instruction set, the former translates into vectorby-vector multiplications with interleaved operands, requiring transposition of the inputs and outputs, and a larger number of registers. The latter can be easily implemented with vector-by-scalar multiplications, requiring much fewer permutation instructions and less rigid instruction scheduling. It is easily seen that in the context of matrix multiplications, Algorithm 1 is a special case of the inner product approach (cf. Algorithm 3), and Algorithm 2 is a special case of the outer product approach (cf. Algorithm 4). We also call them accordingly.

Algorithm 3 Inner-product-based matrix-matrix multiplication.

1: for  $i_0 = 0, ..., n_0 - 1$  do 2: for  $i_1 = 0, ..., n_1 - 1$  do 3: for  $i_2 = 0, ..., n_2 - 1$  do 4:  $A[i_0][i_1] = C[i_0][i_1] + A[i_0][i_2]B[i_2][i_1]$ 5: end for 6:  $\triangleright$  Inner product of the vectors  $A[i_0][-]$  and  $B[-][i_1]$ . 7: end for 8: end for

Algorithm 4 Outer-product-based matrix-matrix multiplication.

1: for  $i_2 = 0, ..., n_2 - 1$  do 2: for  $i_0 = 0, ..., n_0 - 1$  do 3: for  $i_1 = 0, ..., n_1 - 1$  do 4:  $C[i_0][i_1] = C[i_0][i_1] + A[i_0][i_2]B[i_2][i_1]$ 5: end for 6: end for 7:  $\triangleright$  Outer product of the vectors  $A[-][i_2]$  and  $B[i_2][-]$ . 8: end for

## 4.3 Toeplitz Matrices

Let M be an  $m \times n$  matrix over the ring R. We call it a Toeplitz matrix if it takes the form

$$M = \begin{pmatrix} a_{n-1} & a_{n-2} & \cdots & a_1 & a_0 \\ a_n & a_{n-1} & \cdots & a_2 & a_1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{m+n-3} & a_{m+n-4} & \cdots & a_{m-1} & a_{m-2} \\ a_{m+n-2} & a_{m+n-3} & \cdots & a_m & a_{m-1} \end{pmatrix}, \text{ for all possible } i, j, M_{i,j} = M_{i+1,j+1}.$$

We denote M as **Toeplitz**<sub> $m \times n$ </sub> $(a_{m+n-2}, \ldots, a_0)$ .

Toeplitz matrices for weighted convolutions. For a weighted convolution  $\boldsymbol{c} = \boldsymbol{a}\boldsymbol{b} = \left(\sum_{i} a_{i}x^{i}\right)\left(\sum_{i} b_{i}x^{i}\right) \in R[x]/\langle x^{n}-\zeta\rangle$ , we choose an  $n' \geq n$ , zero-pad  $\boldsymbol{a}$  to a size-n' polynomial  $\boldsymbol{a}'$ , and define  $\operatorname{Expand}_{n \to n',\zeta} = \left(\sum_{i < n} b_{i}x^{i},\zeta\right) \mapsto \left(\underbrace{0,\ldots,0}_{n'-n}, b_{n-1},\ldots,b_{0},\zeta b_{n-1},\ldots,\zeta b_{1},\underbrace{0,\ldots,0}_{n'-n}\right)$ . [13] showed that  $\boldsymbol{c}' = \operatorname{Toeplitz}_{n' \times n'}\left(\operatorname{Expand}_{n \to n',\zeta}(\boldsymbol{b})\right)\boldsymbol{a}'$ 

for a size-n' padding c' of c. We can then extract c from c'. Furthermore, **Toeplitz**<sub> $n \times n$ </sub> (Expand<sub> $n \to n, \zeta$ </sub>(-)) (-) is exactly the asymmetric\_mul by [3, Section 4.2]. See [8, Paragraph "A Toeplitz matrix view of asymmetric multiplication", Section 8.3.2] for explanations.

## 4.4 Small-Dimensional Cases

To eplitz matrix–vector multiplications are extensively used in our implementations. For a fast polynomial ring transformation resulting weighted convolutions, we apply the outer-product-based Toeplitz matrix–vector multiplication. Existing works [3,14,16] applied the inner product approach with pre-and posttransposes. The Toeplitz structure admits fast construction of the full matrix. For a weighted convolution over  $x^4 - \zeta$ , we apply  $\mathtt{Expand}_{4\to 4,\zeta}$  with ext instructions, and accumulate vector-by-scalar products. Algorithm 5 is an illustration.

<b>Algorithm 5</b> Outer product approach for $R[x]/\langle x^4 - \zeta \rangle$ .			
<b>Inputs:</b> $a = a_0 + a_1x + a_2x^2 + a_3x^3$ , $b = b_0 + b_1x + b_2x^2 + b_3x^3$ . <b>Outputs:</b> $c = ab \mod (x^4 - \zeta)$ .

Generally speaking, once the Toeplitz matrix is constructed via exts or memory loads (recall that we can instead store an  $n \times n$  Toeplitz matrix as an array of 2n-1 elements), vector-by-scalar multiplications significantly reduce the register pressure and remove the follow up permutation instructions. We illustrate the differences between inner-product-based and outer-product-based Toeplitz matrix-vector multiplication for

$$\begin{pmatrix} a_0 & a'_1 & a'_2 & a'_3 \\ a_1 & a_0 & a'_1 & a'_2 \\ a_2 & a_1 & a_0 & a'_1 \\ a_3 & a_2 & a_1 & a_0 \end{pmatrix} \begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \end{pmatrix}$$

where  $a'_1 = \zeta a_3, a'_2 = \zeta a_2$ , and  $a'_3 = \zeta a_1$  for the weighted convolutions defined in  $R[x]/\langle x^4 - \zeta \rangle$ . Figure 2 illustrates the register view of inner-product-based Toeplitz matrix-vector multiplication and Figure 1 for the outer-product-based one. For Figure 2, we apply  $\log_2 4 \cdot \frac{4}{2} = 4$  pairs of (trn1, trn2) to each operand to reach the register view. While applying vector-by-vector multiplications, the

#### 10 Han-Ting Chen, Yi-Hua Chung, Vincent Hwang, and Bo-Yin Yang

interleaved operands occupy 11 registers and the interleaved partial results occupy 4 or 8 registers (this depends on the coefficient ring). Finally, we also need to transpose the interleaved results with 4 pairs of (trn1, trn2). On the other hand, Figure 1 requires no additional permutations and avoids the interleaved operands and results. This implies nearly no permutation instructions and very low register pressure.

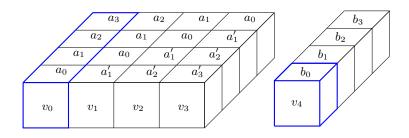

Fig. 1: Outer-product-based Toeplitz matrix-vector multiplication via vectorby-scalar multiplication. No permutations are required once we have data in registers  $v_0, \ldots, v_3$ . We only need 5 registers  $v_0, \ldots, v_4$  for holding the operands and 1 or 2 registers for the partial results.

## 4.5 Large-Dimensional Toeplitz Transformation

There are several benefits when working on Toeplitz matrices. Firstly, we only need to store m + n - 1 coefficients  $M_{m-1,0}, \ldots, M_{0,0}, \ldots, M_{0,n-1}$  of the matrix. Secondly, additions/subtractions of two Toeplitz matrices require only m + n - 1 additions/subtractions in R. Finally, submatrices from adjacent rows and columns are also Toeplitz matrices. These properties enable efficient divide-and-conquer computations when the dimension is large.

For the sake of generality, multiplying two polynomials  $a, b \in R[x]_{<k}$  will be considered as  $ab \in R[x]_{<n}$  with  $n \ge 2k - 1$ . Given an  $a \in R[x]_{<k}$ , we write  $(a, -): R^k \to R^n$  for the module homomorphism  $b \mapsto ab$  and  $(a, -)^*$  its transpose. Suppose we have an *R*-algebra *S* where multiplications are much faster than in  $R[x]_{<n}$ , the Toeplitz matrix-vector product (TMVP) can be defined for an *R*-algebra homomorphism  $f: R[x]_{<n} \to S$  with  $f|_{R[x]_{<k}}$  a monomorphism.

**Definition 1.** Let S be an R-algebra and  $f: R[x]_{\leq n} \to S$  be an R-algebra homomorphism, with  $f_k := f|_{R[x]_{\leq k}} : R[x]_{\leq k} \to S$  a monomorphism. Furthermore, let  $\operatorname{rev}_{k \to k} : R^k \to R^k$  be the index reversal map and  $\operatorname{id}_{m \to n} : R^m \to R^n$  be the inclusion (pad 0's) map for  $m \leq n$ . The TMVP associated with f refers to the following module homomorphisms:

$$\left(\operatorname{\mathbf{Toeplitz}}_{k\times k}(-)\right)(a) = \operatorname{rev}_{k\times k} \circ f_k^* \circ (f_k(a), -)^* \circ (f^{-1})^* \circ \operatorname{id}_{(2k-1)\to n}$$

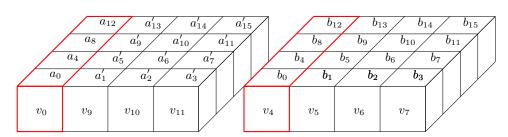

Fig. 2: Inner-product-based Toeplitz matrix-vector multiplication via vectorby-vector multiplication. One load  $(a_0, \ldots, a_3), \ldots, (a_{12}, \ldots, a_{15})$  into registers  $(v_0, \ldots, v_3)$ , and transpose the registers as a  $4 \times 4$  matrix. Same for  $(v_4, \ldots, v_7)$  holding  $(b_0, \ldots, b_3), \ldots, (b_{12}, \ldots, b_{15})$  and  $(v_8, \ldots, v_{11})$  holding  $(c_0, \ldots, c_3), \ldots, (c_{12}, \ldots, c_{15})$ . Notice that we need to hold the registers  $v_0, v_4, \ldots, v_{11}$  for computing  $a_0b_0+c_1b_1+c_2b_2+c_3b_3$ . Therefore, we need 11 registers (we don't need  $(c_0, c_4, c_8, c_{12})$ ) for the operands. Since we also need registers for holding the partial results (4 registers for  $\mathbb{Z}_{2^{16}}$  and 8 registers otherwise), the register pressure is high and forbids us to generalize to size-16 computations.

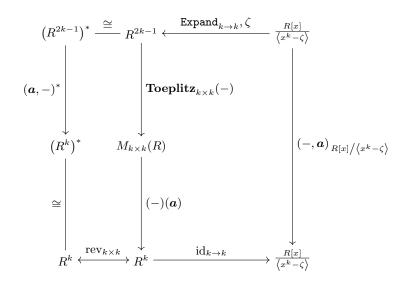

We call  $(f^{-1})^* \circ \operatorname{id}_{(2k-1) \to n}$  split-matrix,  $f_k(a)$  split-vector,  $(f_k(a), -)^*$  base multiplication, and  $f_k^*$  interpolation. If n = 2k - 1,  $f = \operatorname{\mathbf{TC}}_{(2k-1)\times(2k-1)}$ , then this is the k-way Toeplitz-TC matrix-vector product [12,13]. Generally, any *R*algebra monomorphism suffices. See Appendices B for a formal proof and C for examples. We go through a higher-level overview of the idea.

Since f is a ring monomorphism, we implement the module homomorphism (a, -) as  $\operatorname{id}_{n \to (2k-1)} \circ f^{-1} \circ (f_k(a), -) \circ f_k$ , take the transpose of (a, -), and relate  $(a, -)^*$  to the Toeplitzation **Toeplitz**\_{k \times k}(-) and the right-vector-multiplication (-)(a). This allows us to convert any fast computation for (a, -) into something for  $(\operatorname{Toeplitz}_{k \times k}(-))(a)$ . Since  $(\operatorname{Toeplitz}(-))(a) = \operatorname{rev}_{k \times k} \circ (a, -)^*$ , and  $(-, a)_{R[x]/\langle x^k - \zeta \rangle} = \operatorname{id}_{k \to k} \circ (\operatorname{Toeplitz}(-))(a) \circ \operatorname{Expand}_{k \to k, \zeta}$  as shown in Figure 3, we eventually have a fast computation for  $(-, a)_{R[x]/\langle x^k - \zeta \rangle}$ .

## 5 Implementations

We propose two implementations for ntruhps2048677 with 16-bit arithmetic modulo 65536: (i) Toom-Cook implements Toom-Cook with the splitting sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$ , and (ii) Toeplitz-TC computes the Toeplitz matrixvector product derived from Toom-Cook. Our Toom-Cook applies a more aggressive divide-and-conquer than prior works [9,14] by carefully choosing the point set for evaluations. Our Toeplitz-TC reveals the benefit of vector-by-scalar multiplications, which is more significant than the findings of [13].

For ntruhrss701, we implement the Toeplitz-TC approach with the same splitting sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$  with the 3's referring to 3-way Karatsuba instead of Toom-3. We skip the Toom-Cook approach since it is obviFig. 3: Relations between  $(-, a)_{R[x]/\langle x^k - 1 \rangle}$ , (Toeplit $\mathbf{z}_{k \times k}(-)$ )(a), and  $(a, -)^*$ .

ously not worth implementing given the experience from ntruhps2048677. Since the implementation Toeplitz-TC of ntruhrss701 is very close to the one for ntruhps2048677, we skip the description for ntruhrss701.

Section 5.1 describes the Toom-Cook approach, and Section 5.2 describes the Toeplitz-TC approach. Additionally, we summarize existing strategies multiplying polynomials in ntruhps2048677 in Table 1, and compare the general ideas among Toom-Cook and Toeplitz-TC in Appendix E.

#### 5.1 Toom-Cook

We first describe our chosen Toom–Cook splitting sequence and implementation considerations. We then detail our memory optimization for the interpolation of  $\mathbf{TC}^{-1}$ .

**Chosen splitting sequence.** We choose the splitting sequence Toom-5  $\rightarrow$  two Toom-3's  $\rightarrow$  Karatsuba. We first zero-pad the size-677 polynomials to size-720 for ease of vectorization and compute in  $\mathbb{Z}_{2^{16}}$ . Since the coefficient ring of ntruhps2048677 is  $\mathbb{Z}_{2048}$  and  $\frac{2^{16}}{2048} = 2^5$ , divisions by  $2^e$  for  $e = 0, \ldots, 5$  translate into shifting e bits. We choose the splitting sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$ . Our Toom-Cook consists of one layer of  $\mathbf{TC}_{9\times5}$ , two layers of  $\mathbf{TC}_{5\times3}$ 's, one layer of  $\mathbf{TC}_{3\times2}$ , 675 size-8 schoolbooks, one layer of  $\mathbf{TC}_{3\times3}^{-1}$ , two layers of  $\mathbf{TC}_{5\times5}^{-1}$ 's, and one layer of  $\mathbf{TC}_{9\times9}^{-1}$ . We choose the point sets  $\{0, \pm 1, \pm 2, \pm \frac{1}{2}, 3, \infty\}$  (cf. Section 3.2) for  $\mathbf{TC}_{9\times5}$  and  $\{0, \pm 1, 2, \infty\}$  for  $\mathbf{TC}_{5\times3}$ . The interpolation matrices  $\mathbf{TC}_{9\times9}^{-1}$ ,  $\mathbf{TC}_{5\times5}^{-1}$ ,

Table 1: Overview of divide-and-conquer strategies multiplying polynomials in  $R[x]_{<720}$  for ntruhps2048677. We first start with  $R[x]_{<720}$  and alternatingly list all the number of subproblems of divide-and-conquer and the resulting ring. For example, the sequence  $R[x]_{<720}$ ,  $4 \rightarrow 7$ ,  $R[x]_{<180}$  means that size-720 polynomials are first sectioned into four size-180 polynomials, and mapped to seven size-180 polynomials, and the resulting polynomial multiplications defined in  $R[x]_{180}$ .

	[13]	[14]	This work
Ring	$R[x]_{<720}$	$R[x]_{<720}$	$R[x]_{<720}$
Divide-and-conquer	$4 \rightarrow 7$	$3 \rightarrow 5$	$5 \rightarrow 9$
Ring	$R[x]_{<180}$	$R[x]_{<240}$	$R[x]_{<144}$
Divide-and-conquer	$3 \rightarrow 5$	$4 \rightarrow 7$	$3 \rightarrow 5$
Ring	$R[x]_{<60}$	$R[x]_{<60}$	$R[x]_{<48}$
Divide-and-conquer	$3 \rightarrow 5$	$2 \rightarrow 3$	$3 \rightarrow 5$
Ring	$R[x]_{<20}$	$R[x]_{<30}$	$R[x]_{<16}$
Divide-and-conquer	$2 \rightarrow 3$	$2 \rightarrow 3$	$2 \rightarrow 3$
Ring	$R[x]_{<10}$	$R[x]_{<15}$	$R[x]_{<8}$

and  $\mathbf{TC}_{3\times3}^{-1}$  incur 3-, 1-, and 0-bit losses of precision, respectively. These add up to 5 bits, allowing us to invert correctly.

Comparisons to prior splitting sequence [14]. [14] treated each polynomial as a size-720 polynomial, and applied Toom–Cook with the splitting sequence  $3 \rightarrow 4 \rightarrow 2 \rightarrow 2$ . The polynomial size goes down to 240 after the Toom-3, 60 after the Toom-4, and 15 after two Karatsuba's. Since 60 is not a multiple of 8, [14] basically padded to size-64 polynomials before Karatsuba. In this paper, we instead split via the sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$  down to size-8 schoolbooks. Our evaluation points for Toom-5 has the same precision loss as Toom-4. This is 1 fewer bit than the standard  $\{0, \pm 1, \pm 2, \pm 3, 4, \infty\}$ . We also avoid zero-padding in vectorization. We merge the two Toom-3 layers (for both  $\mathbf{TC}_{5\times 3}$  and  $\mathbf{TC}_{5\times 5}^{-1}$ ) to reduce memory operations.

Memory optimizations for interpolations. Let k|n, g' be a polynomial of degree at least  $\frac{2n}{k} - 1$ , and  $R' = R[x]/\langle g' \rangle$ . Recall that  $\mathbf{TC}_{(2k-1)\times k}$  computes  $R[x]/\langle x^{\frac{n}{k}} - y \rangle [y] \hookrightarrow R'[y]/\langle \prod_{i=0}^{2k-2} (y-s_i) \rangle \cong \prod_{i=0}^{2k-2} R'[y]/\langle y-s_i \rangle$  and results in computations in  $R[x]/\langle g' \rangle$ . After examining the source code, we find that prior works [9, 14] inverted the steps  $\cong$  and  $\hookrightarrow$  separately. Algorithm 6 is an illustration. Inverting  $\cong$  means applying the interpolation matrix and inverting  $\hookrightarrow$  means accumulating the overlapped coefficients while substituting y with  $x^{\frac{n}{k}}$  in each of the polynomials in  $R[x]/\langle g' \rangle$ . We instead alternate between the

inversions of  $\cong$  and  $\hookrightarrow$  to reduce memory operations, in essence merging two layers of computations.

7: end for	8: end for
8: $\triangleright$ Memory read and write.	9: for $j = \{0, \dots, 5\}$ do
9: end for	10: $c[2j] = r[j]$
	11: end for
	12: $\triangleright$ Memory write.
	13: $r[0-4] = TC_{5 \times 5}^{-1}(p_0[1], \dots, p_4[1])$
	14: $\triangleright$ Memory read.
	15: for $j \leftarrow 0$ to 4 do
	16: $c[2j+1] = r[j]$
	17: end for
	18: $\triangleright$ Memory write.

We illustrate the idea with k = 3 and n = 6. Suppose we have five size-3 polynomials  $w_i = \sum_{j=0}^2 w_{i,j} x^j \in R[x]/\langle g' \rangle$  after the base multiplications. We show how to interleave the inversions of  $\cong$  and  $\hookrightarrow$  for reducing memory operations.

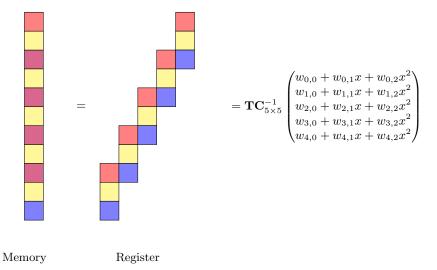

We first apply  $\mathbf{TC}_{5\times 5}^{-1}$  to the 5-tuples  $(w_{0,0}, \ldots, w_{4,0})$  and  $(w_{0,2}, \ldots, w_{4,2})$ , and add the overlapped coefficients according to  $y \sim x^2$  before storing the results to memory. Then, we apply  $\mathbf{TC}_{5\times 5}^{-1}$  to the 5-tuple  $(w_{0,1}, \ldots, w_{4,1})$ . Since  $\mathbf{TC}_{5\times 5}^{-1}(w_{0,1}, \ldots, w_{4,1})$  do not overlap with other coefficients, we store them to memory immediately. Figure 4 is an illustration, and Algorithm 7 goes through the detailed implementation. For large *n* fewer coefficients will not overlap others, but the merging of two computations still saves memory overhead.

## 5.2 Toeplitz-TC

We apply the Toeplitz matrix-vector product with **TC**'s as the underlying monomorphisms and choose the same splitting sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$ . We call it Toeplitz-TC.

Our Toeplitz-TC with the splitting sequence  $5 \rightarrow 3 \rightarrow 3 \rightarrow 2$ . Algorithm 8 describes our Toeplitz-TC implementation. Essentially, we regard

size-677 polynomials a and b as size-720 polynomials. In practice, we zero-pad a and b to length 680 and omit the computations involving the indices 680, ..., 719. Then, we apply one layer of Toeplitz-TC-5, two layers of Toeplitz-TC-3's, and one layer of Toeplitz-TC-2. Algorithm 9 describes our Toeplitz-TC-3-3-2 following Toeplitz-TC-5.

Each steps of Algorithms 8 and 9 is implemented as a subroutine. We merge computations while using all available registers without register spills. Initializations to zeros and the corresponding computations are also omitted for efficiency. While applying  $\mathbf{TC}$ ,  $\mathbf{TC}'^{-1*}$ , and  $\mathbf{TC}'^*$ , we prefer shifts over multiplications and reuse intermediate values. We refer to Appendix D for the resulting matrices.

```
Algorithm 8 Toeplitz-TC for ntruhps2048677.

Input: size-720 polynomials a, b.

Output: the size-677 polynomial c = ab \mod (x^{677} - 1).

1: Declare uint16_t buff_a[9] [288], buff_b[9] [144], buff_c[9] [144].

2: buff_a[0-8] [0-287] = TC_{9\times9}^{-1*} (a)

3: \triangleright See Section 4.5 for definition.

4: buff_b[0-8] [0-143] = TC_{9\times5} (b)

5: for i = \{0, ..., 8\} do

6: buff_c[i] [0-143] = Toeplitz-TC-3-3-2 (buff_a[i] [0-287], buff_b[i] [0-143])

7: end for

8: c[0-676] = TC_{9\times5}^* (buff_c[0-8] [0-143])
```

Algorithm 9 Toeplitz-TC-3-3-2.

16

Input: a 144 × 144 Toeplitz matrix M, and a size-144 vector v. Output: the size-144 vector  $c = M \cdot v$ . 1: Declare uint16\_t M1[5] [96], M2[5] [5] [3] [16]. 2: Declare uint16\_t v1[5] [5] [16], c1[5] [5] [16]. 3: M1[0-4] [0-95] =  $\mathbf{TC}_{5\times5}^{-1*}$  (M[0-143] [0-143]) 4: for  $i = \{0, ..., 4\}$  do 5: M2[i] [0-4] [0-2] [0-15] =  $(\mathbf{TC}_{3\times3}^{-1*} \circ \mathbf{TC}_{5\times5}^{-1*})$  (M1[i] [0-95]) 6: end for 7: v1[0-4] [0-4] [0-15] =  $(\mathbf{TC}_{5\times3} \circ \mathbf{TC}_{5\times3})$  (v) 8: c1[i] [j] [0-15] =  $\mathbf{TC}_{3\times2}^{*}$  (M2[i] [j] [0-2] [0-15]  $\cdot \mathbf{TC}_{3\times2}$  (b1[i] [j] [0-15])) 9: c[0-143] =  $(\mathbf{TC}_{5\times3}^{*} \circ \mathbf{TC}_{5\times3}^{*})$  (c1[0-4] [0-4] [0-15])

Comparisons to [13]. [13] implemented the Toeplitz matrix-vector product with  $\mathbf{TC}_{(2k-1)\times k}$  as the underlying monomorphisms on Cortex-M4, but they chose the splitting sequence  $4 \rightarrow 3 \rightarrow 2 \rightarrow 2$ . We improve the efficiency by applying a more aggressive splitting sequence. For the first layer, we use Toeplitz-TC-5 instead of Toeplitz-TC-4. Both strategies yield 3-bit losses. Although our  $\mathbf{TC}_{9\times 9}^{-1*}$ ,  $\mathbf{TC}_{9\times 5}$ , and  $\mathbf{TC}_{9\times 5}^*$  require more multiplications, we have a smaller number of schoolbooks, which is the bottleneck of the computation. Compared to [13], our Cortex-A72 implementation reaches the best performance with size-8 schoolbooks is the descent of size-16 ones. Also, [13] used  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$ ,  $\mathbf{TC}_{(2k-1)\times k}$  and  $\mathbf{TC}_{(2k-1)\times k}^*$  to compute while we multiply some constants to the precomputed matrices for easier computation.

## 6 Results

We present the performance numbers in this section. We focus on polynomial multiplications, leaving the fast constant-time GCD [5] as future work

## 6.1 Benchmark Environment

We use the Raspberry Pi 4 Model B featuring the quad-core Broadcom BCM2711 chipset. It comes with a 32 kB L1 data cache, a 48 kB L1 instruction cache, and a 1 MB L2 cache and runs at 1.5 GHz. For hashing, we use the **aes**, **sha2**, and **fips202** from PQClean [10] without any optimizations due to the lack of corresponding cryptographic units. For the randombytes, [3] used the **randombytes** from SUPERCOP which in turn used **chacha20**. We extract the conversion from **chacha20** into **randombytes** from SUPERCOP and replace **chacha20** with our optimized implementations using the pipelines IO/I1, FO/F1. We use the cycle counter of the PMU for benchmarking. Our programs are compilable with GCC 10.3.0, GCC 11.2.0, Clang 13.1.6, and Clang 14.0.0. We report numbers for the binaries compiled with GCC 11.2.0.

## 6.2 Performance of Vectorized Polynomial Multiplications

Table 2 summarizes the performance of vectorized polynomial multiplications. All of our implementations outperform the state-of-the-art Toom-Cook [14]. For ntruhps2048677, our Toeplitz-TC and Toom-Cook are  $2.18 \times$  and  $1.56 \times$  faster than [14]. Comparing Toeplitz-TC and Toom-Cook based on the same splitting sequence, the result is consistent to [13]. But the most significant reason is the use of vector-by-scalar multiplications. This finding is new. For ntruhrss701, we outperform [14]'s implementation by  $2.23 \times$ .

ntruhps2048677 ntruhrss701

Table 2: Overview of polymuls.

## 6.3 Performance of Schemes

Before comparing the overall performance, we first illustrate the performance numbers of some other critical subroutines. Most of our optimized implementations of these subroutines are not seriously optimized except for parts involving polynomial multiplications. We simply translate existing techniques and AVX2-optimized implementations into Neon. Notice that inversions over  $\mathbb{Z}_2$  and  $\mathbb{Z}_3$ , and sorting networks are implemented in a generic sense. With fairly little effort, they can be used for other parameter sets. Table 3 summarizes the performance of inversions and sorting network.

Operation	Ref	Ours	Ref	Ours
	ntruhps2	2048677	ntruhr	ss701
			3938579	
poly_R2_inv	2791906	136776	3175330	140290
poly_S3_inv	4153823	482005	4765259	503590
crypto_sort_int32	104 691	17819	-	-

Table 3: Performance of inversions and sorting network in NTRU.

**Inversions.** For ntruhps2048677, we need one inversion in  $\mathbb{Z}_{2048}[x]/\langle x^{677}-1\rangle$ and one inversion in  $\mathbb{Z}_3[x]/\langle \frac{x^{677}-1}{x-1}\rangle$ . The inversion in  $\mathbb{Z}_{2048}[x]/\langle x^{677}-1\rangle$  consists of one inversion in  $\mathbb{Z}_2[x]/\langle x^{677}-1\rangle$  and lifting to  $\mathbb{Z}_{2048}[x]/\langle x^{677}-1\rangle$  with

17

eight polynomial multiplications since the coefficient ring is  $\mathbb{Z}_{2048}$ . We use the 1-bit form of  $\mathbb{Z}_2$  for the inversion over  $\mathbb{Z}_2$  without any algorithmic improvements and obtain a 20.41× speedup, leading to 10.27× overall speedup for the inversion over  $\mathbb{Z}_{2048}$ . The rest of the improvement for inversion over  $\mathbb{Z}_{2048}$  comes from our improved polynomial multiplications (we use Toeplitz-TC here). For the inversion in  $\mathbb{Z}_3[x]/\langle \frac{x^{677}-1}{x-1} \rangle$ , we use bitsliced implementation and obtain a 8.6× speedup. For ntruhrss701, we outperform obtain 22.63×, 10.04×, 9.46× performance improvement for inversions over  $\mathbb{Z}_2$ ,  $\mathbb{Z}_{8192}$ , and  $\mathbb{Z}_3$ , respectively.

Sorting Network. We translate AVX2-optimized sorting network into Neon.

**Performance of ntruhps2048677 and ntruhrss701.** Table 4 summarizes our ntruhps2048677 and ntruhrss701. We compare our Toeplitz-TC to the existing NTRU implementations on Cortex-A72 [14]. For ntruhps2048677, our key generation is 7.67× faster. The main contribution is our optimized inversions, multiplications lifting the inverse in  $\mathbb{Z}_2[x]/\langle x^{677} - 1 \rangle$ , followed by polynomial multiplications in  $\mathbb{Z}_{2048}[x]/\langle x^{677} - 1 \rangle$  (for lifting) and sorting network. Our ntruhps2048677 encapsulation is 2.48× faster. The main contribution is the sorting network followed by polynomial multiplications. Our ntruhps2048677 decapsulation is 1.77× faster. The improvement entirely comes from the improved polynomial multiplications. For ntruhrss701, our key generation, encapsulation, and decapsulation are 7.99×, 1.47×, and 1.56× faster than [14], respectively.

## A Toom–Cook Matrices

The example below has k = 5 and  $\{s_i\} = \{0, \pm 1, \pm 2, \pm \frac{1}{2}, 3, \infty\}$ . Notice that at  $y = \pm \frac{1}{2}$ , the evaluation is customarily  $\boldsymbol{a} \mapsto (\pm 2)^{k-1} \boldsymbol{a} (\pm \frac{1}{2})$  rather than  $\boldsymbol{a} \mapsto \boldsymbol{a} (\pm \frac{1}{2})$ , and computes the product  $(\pm 2)^{2k-2} \boldsymbol{a} \boldsymbol{b} (\pm \frac{1}{2})$  rather than  $\boldsymbol{a} \boldsymbol{b} (\pm \frac{1}{2})$ . The matrices are therefore adjusted accordingly. The resulting  $\mathbf{TC}_{9\times 5}$  and  $\mathbf{TC}_{9\times 9}^{-1}$  are given as follows.

$$\mathbf{TC}_{9\times5} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 \\ 1 & 2 & 4 & 8 & 16 \\ 1 & 3 & 9 & 27 & 81 \\ 16 & 8 & 4 & 2 & 1 \\ 16 & -8 & 4 & -2 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \mathbf{TC}_{9\times9}^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 2 & 4 & 8 & 16 & 32 & 64 & 128 & 256 \\ 1 & -2 & 4 & -8 & 16 & -32 & 64 & -128 & 256 \\ 1 & 3 & 9 & 27 & 81 & 243 & 729 & 2187 & 6561 \\ 256 & 128 & 64 & 32 & 16 & 8 & 4 & 2 & 1 \\ 256 & -128 & 64 & -32 & 16 & -8 & 4 & -2 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} ^{-1}$$

## **B** Proof for the Toeplitz Transformation

For an algebra homomorphism  $f: R[x]_{< n} \to S$  with  $f_k \coloneqq f|_{R[x]_{< k}}$  a monomorphism, and module homomorphism  $(\boldsymbol{a}, -) = \begin{cases} R^k \to R^n \\ \boldsymbol{b} \mapsto \boldsymbol{a}\boldsymbol{b} \end{cases}$  where  $n \ge 2k - 1$ , we have

$$\left(\operatorname{\mathbf{Toeplitz}}_{k\times k}(-)\right)(\boldsymbol{a}) = \operatorname{rev}_{k\times k} \circ f_k^* \circ (f_k(\boldsymbol{a}), -)^* \circ (f^{-1})^* \circ \operatorname{id}_{(2k-1)\to n}.$$

*Proof.* Observe  $(\boldsymbol{a}, -)^* = f_k^* \circ (f_k(\boldsymbol{a}), -)^* \circ (f^{-1})^* \circ \mathrm{id}_{(2k-1)\to n}$ , it remains to show (**Toeplitz**\_{k\times k}(-))(\boldsymbol{a}) = \mathrm{rev}\_{k\times k} \circ (\boldsymbol{a}, -)^\*. Let  $\boldsymbol{z} = (z_0, \ldots, z_{2k-2})$ ,  $[k] = \{0, \ldots, k-1\}$ , and  $\boldsymbol{0}_{m_0,m_1}$  the  $m_0 \times m_1$  matrix of zeros. We have:

$$(\operatorname{rev}_{k \times k} \circ \operatorname{Toeplitz}_{k \times k}(z)) (a)$$

$$= (z_{i+j})_{(i,j) \in [k]^2} (a_j)_{(j,0) \in [k] \times [1]}$$

$$= \left( \sum_{j \in [k]} z_{i+j} a_j \right)_{(i,0) \in [k] \times [1]}$$

$$= \sum_{j \in [k]} (z_{i+j} a_j)_{(i,0) \in [k] \times [1]}$$

$$= \sum_{j \in [k]} (\mathbf{0}_{k,j} \ a_j I_k \ \mathbf{0}_{k,k-j-1}) (z_h)_{(h,0) \in [2k-1] \times [1]}$$

$$= \operatorname{Toeplitz}_{k \times (2k-1)} (\mathbf{0}_{1,k-1}, a_0, \dots, a_{k-1}, \mathbf{0}_{1,k-1}) (z_h)_{(h,0) \in [2k-1] \times [1]}$$

$$= (a, -)^*(z).$$

Applying  $rev_{k \times k}$  from the left finishes the proof (cf. [18, Theorem 6]).

# C Examples of Toeplitz Transformations

We give some examples of f's implementing  $\begin{pmatrix} z_1 & z_2 \\ z_0 & z_1 \end{pmatrix} \begin{pmatrix} a_1 \\ a_0 \end{pmatrix}$ :

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} z_1 & z_2 \\ z_0 & z_1 \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} a_0 & 0 & 0 \\ 0 & a_0 + a_1 & 0 \\ 0 & 0 & a_1 \end{pmatrix} \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & 0 \\ 0 & -1 & 1 \end{pmatrix} \begin{pmatrix} z_0 \\ z_1 \\ z_2 \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega_3 & \omega_3^2 \end{pmatrix} \begin{pmatrix} a_0 + a_1 & 0 & 0 \\ 0 & a_0 + \omega_3 a_1 & 0 \\ 0 & 0 & a_0 + \omega_3^2 a_1 \end{pmatrix} \mathbf{F}_3^{-1} \begin{pmatrix} z_0 \\ z_1 \\ z_2 \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & \omega_4 & \omega_4^2 & \omega_4^3 \end{pmatrix} \begin{pmatrix} a_0 + a_1 & 0 & 0 & 0 \\ 0 & a_0 + \omega_4 a_1 & 0 & 0 \\ 0 & 0 & a_0 + \omega_4^2 a_1 & 0 \\ 0 & 0 & 0 & a_0 + \omega_4^3 a_1 \end{pmatrix} \mathbf{F}_4^{-1} \begin{pmatrix} z_0 \\ z_1 \\ z_2 \\ 0 \end{pmatrix}$$

where  $\mathbf{F}_{k}^{-1} = \left(\mathbf{F}_{k}^{-1}\right)^{T}$  is the inverse of the cyclic size-k FFT.

# D Matrices Used in Our TMVP

Instead of computing  $\mathbf{TC}^*$  and  $(\mathbf{TC}^{-1})^*$  directly, we change the matrices somewhat. Divisions by powers of 2 are postponed, so are divisions by some odd numbers, since multiplying elements of **Toeplitz** $(a_{2n-2}, \ldots, a_0)$  by constants is rather expensive. We also substitute some shifts for multiplications and use temporary values more efficiently.

Let  $\mathbf{D}_{\text{eval5}} = \text{diag}\left(b(0), b(1), b(-1), b(2), b(-2), b(3), 16b\left(\frac{1}{2}\right), 16b\left(-\frac{1}{2}\right), b(\infty)\right)$ and  $\mathbf{Scale}_{9\times9} = \text{diag}\left(4, 72, 72, 360, 360, 4200, 360, 360, 4\right)$ . Our Toeplitz-TC-5 formula is as follows.

$$\begin{pmatrix} z_4 & z_3 & z_2 & z_1 & z_0 \\ z_5 & z_4 & z_3 & z_2 & z_1 \\ z_6 & z_5 & z_4 & z_3 & z_2 \\ z_7 & z_6 & z_5 & z_4 \end{pmatrix} \begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \end{pmatrix} = \frac{1}{8} \operatorname{rev}_{5 \times 5} \mathbf{TC}'^*_{9 \times 5} \begin{pmatrix} P_0 \\ \frac{1}{9}P_1 \\ \frac{1}{9}P_2 \\ \frac{1}{45}P_3 \\ \frac{1}{45}P_4 \\ \frac{1}{525}P_5 \\ \frac{1}{45}P_6 \\ \frac{1}{45}P_7 \\ P_8 \end{pmatrix}, \qquad \text{where}$$

$$\operatorname{rev}_{5\times 5} \mathbf{TC}_{9\times 5}^{\prime *} = \begin{pmatrix} 0 \ 1 \ 1 \ 16 \ 16 \ 81 \ 1 \ 1 \ 2 \\ 0 \ 1 \ -1 \ 8 \ -8 \ 27 \ 2 \ -2 \ 0 \\ 0 \ 1 \ 1 \ 4 \ 4 \ 9 \ 4 \ 4 \ 0 \\ 2 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 6 \ -16 \ 0 \end{pmatrix}, \begin{pmatrix} P_0 \\ P_1 \\ P_2 \\ P_3 \\ P_4 \\ P_5 \\ P_6 \\ P_7 \\ P_8 \end{pmatrix} = \mathbf{D}_{eval5} \mathbf{TC}_{9\times 9}^{\prime -1*} \begin{pmatrix} z_8 \\ z_7 \\ z_6 \\ z_5 \\ z_4 \\ z_3 \\ z_2 \\ z_1 \\ z_0 \end{pmatrix},$$

$$\mathbf{TC}_{9\times9}^{\prime-1*} = \begin{pmatrix} 4 & -\frac{4}{3} & -21 & 7 & 21 & -7 & -4 & \frac{4}{3} & 0\\ 0 & -24 & -16 & 110 & 68 & -58 & -16 & 8 & 0\\ 0 & 12 & -16 & -47 & 68 & -5 & -16 & 4 & 0\\ 0 & 6 & 1 & -31 & -5 & 29 & 4 & -4 & 0\\ 0 & -\frac{6}{5} & 1 & \frac{29}{5} & -5 & -\frac{19}{5} & 4 & -\frac{4}{5} & 0\\ 0 & -4 & 0 & 21 & 0 & -21 & 0 & 4 & 0\\ 0 & \frac{12}{5} & 4 & -\frac{23}{5} & -5 & \frac{13}{5} & 1 & -\frac{2}{5} & 0\\ 0 & -\frac{12}{7} & 4 & 1 & -5 & 1 & 1 & -\frac{2}{7} & 0\\ 0 & 12 & -4 & -63 & 21 & 63 & -21 & -12 & 4 \end{pmatrix} = \mathbf{Scale}_{9\times9}\mathbf{TC}_{9\times9}^{-1*}.$$

Let  $\mathbf{Scale}_{5\times 5} = \operatorname{diag}(2, 6, 2, 6, 1)$  and  $\mathbf{D}_{\text{eval}3} = \operatorname{diag}(b(0), b(1), b(-1), b(-2), b(\infty))$ . We use the following Toeplitz-TC-3 formula.

$$\begin{pmatrix} z_2 & z_1 & z_0 \\ z_3 & z_2 & z_1 \\ z_4 & z_3 & z_2 \end{pmatrix} \begin{pmatrix} b_0 \\ b_1 \\ b_2 \end{pmatrix} = \frac{1}{2} \operatorname{rev}_{3 \times 3} \mathbf{TC}_{5 \times 3}^{\prime *} \begin{pmatrix} P_0 \\ \frac{1}{3} P_1 \\ P_2 \\ \frac{1}{3} P_3 \\ P_4 \end{pmatrix}$$

where

$$\operatorname{rev}_{3\times 3} \mathbf{TC}_{5\times 3}^{\prime*} = \begin{pmatrix} 0 \ 1 & 1 & 4 & 2 \\ 0 \ 1 & -1 & -2 & 0 \\ 1 \ 1 & 1 & 1 & 0 \end{pmatrix}, \begin{pmatrix} P_0 \\ P_1 \\ P_2 \\ P_3 \\ P_4 \end{pmatrix} = \mathbf{D}_{\text{eval}3} \mathbf{TC}_{5\times 5}^{\prime-1*} \begin{pmatrix} z_4 \\ z_3 \\ z_2 \\ z_1 \\ z_0 \end{pmatrix},$$
$$\begin{pmatrix} 2 \ 1 & -2 & -1 & 0 \\ 0 \ 2 & 3 & 1 & 0 \\ 0 \ 2 & 3 & 1 & 0 \\ 0 \ 2 & 3 & 1 & 0 \\ 0 \ 2 & 3 & 1 & 0 \\ \end{pmatrix} = \mathbf{D}_{\text{eval}3} \mathbf{TC}_{5\times 5}^{\prime-1*} \begin{pmatrix} z_4 \\ z_3 \\ z_1 \\ z_0 \end{pmatrix},$$

$$\mathbf{TC}_{5\times5}^{\prime-1*} = \begin{pmatrix} 0 & 2 & 0 & 1 & 0 \\ 0 & -2 & 1 & 1 & 0 \\ 0 & 1 & 0 & -1 & 0 \\ 0 & -2 & -1 & 2 & 1 \end{pmatrix} = \mathbf{Scale}_{5\times5}\mathbf{TC}_{5\times5}^{-1*}.$$

Let  $\mathbf{D}_{\text{eval2}} = \text{diag}(b(0), b(1), b(\infty))$ . We use the following Toeplitz-TC--2 formula.

$$\begin{pmatrix} z_1 & z_0 \\ z_2 & z_1 \end{pmatrix} \begin{pmatrix} b_0 \\ b_1 \end{pmatrix} = \begin{pmatrix} P_0 + P_1 \\ P_0 + P_2 \end{pmatrix} \text{ where } \begin{pmatrix} P_0 \\ P_1 \\ P_2 \end{pmatrix} = \mathbf{D}_{\text{eval}2} \begin{pmatrix} \mathbf{T} \mathbf{C}_{3 \times 3}^{-1*} \begin{pmatrix} z_2 \\ z_1 \\ z_0 \end{pmatrix} \end{pmatrix}.$$

## E Comparing Toom–Cook and Toeplitz–TC

For Toom–Cook–k, we use the notation  $\boldsymbol{a} = \sum_i a_i x^i, \boldsymbol{b} = \sum_i b_i x^i \in R[x]/\langle x^n - \zeta \rangle$ for the input polynomials, and the weighted convolution  $\boldsymbol{c} = \boldsymbol{a} \boldsymbol{b} \in R[x]/\langle x^n - \zeta \rangle$ for the output polynomial. Let A, B, and C denote the  $n \times 1$  vectors that stores the coefficients of  $\boldsymbol{a}, \boldsymbol{b}$ , and  $\boldsymbol{c}$ .

For Toeplitz–TC–k, we use the notation Z for the input Toeplitz matrix, B for the input vector, and C' = ZB for the output vector.

To analyze the computation of Toom–Cook–k and Toeplitz matrix-vector product using Took–Cook–k, we split the two computation into the following phases: Evaluations. Toom–Cook–k computes  $\mathbf{TC}_{(2k-1)\times k}$  on both A and B to output (2k-1) size-(n/k) vectors. If converted into Toeplitz–TC–k, Toeplitz–TC–k only computes  $\mathbf{TC}_{(2k-1)\times k}$  on the input vector B to output (2k-1) size-(n/k) vectors. For the input Toeplitz matrix Z, Toeplitz–TC–k computes  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$  to output (2k-1)  $(n/k \times n/k)$  Toeplitz matrices. We will analyze the computations of the evaluation step with the interpolation step together later.

Base multiplications. Toom-Cook-k computes vector-to-vector multiplication on two size-(n/k) vectors to output one size-(2n/k) vector. Instead, Toeplitz-TC-k computes matrix-vector product on one  $(n/k \times n/k)$  Toeplitz matrix and one size-(n/k) vector to output one size-(n/k) vector. As mentioned in Section 4.4, vector-by-vector multiplications require two transposing steps while matrix-vector product doesn't. We can easily load any column when implementing Toeplitz-TC. In our experiment, base multiplications are the bottleneck of both algorithms, and Toeplitz-TC significantly outperforms Toom-Cook in base multiplications.

Interpolations. Took–Cook–k computes  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1}$  on (2k-1) size-(2n/k) vectors to output one size-(2n) vector. On the other hand, Toeplitz–TC–k computes  $\mathbf{TC}_{(2k-1)\times k}^*$  on (2k-1) size-(n/k) vectors to output one size-n vector C'. When looking at the evaluation and interpolation together, notice that there are some similar computations. Toom–Cook–k computes  $\mathbf{TC}_{(2k-1)\times k}$  twice and  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1}$  once in total. On the other hand, Toeplitz–TC–k computes  $\mathbf{TC}_{(2k-1)\times(2k-1)}$  once in total. On the other hand, Toeplitz–TC–k computes  $\mathbf{TC}_{(2k-1)\times k}$  once,  $\mathbf{TC}_{(2k-1)\times k}^*$  once and  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$  once in total. We argue that the amount of computation of  $\mathbf{TC}_{(2k-1)\times k}$  and  $\mathbf{TC}_{(2k-1)\times (2k-1)}^*$  are about the same, and we have verified this on Cortex-A72. For  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$  and  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$ , the difference of the amount of computation does not vary a lot when we use Toom–Cook/Toeplitz–TC–2, 3, or 4. However, for Toom–Cook/Toeplitz–TC–5 with the chosen points,  $\mathbf{TC}_{(2k-1)\times(2k-1)}^{-1*}$  allows us to multiply it with some constants that leads to a computation path using the temporary values more efficiently and thus needs fewer instructions and fewer multiplication instructions.

Reductions to target polynomial modulus. For weighted convolutions, Toom-Cook requires an additional step to reduce the size-(2n) vector into to a size-n vector C. On the other hand, Toeplitz-TC requires no such reduction phase. We find that for weighted convolutions, Toeplitz-TC is generally better than Toom-Cook.
