**Abstract.** Deniable Authentication is a highly desirable property for secure messaging protocols: it allows a sender Alice to authentically transmit messages to a designated receiver Bob in such a way that only Bob gets convinced that Alice indeed sent these messages. In particular, it guarantees that even if Bob tries to convince a (non-designated) party Judy that Alice sent some message, and even if Bob gives Judy his own secret key, Judy will not be convinced: as far as Judy knows, *Bob could be making it all up!*

In this paper we study Deniable Authentication in the setting where Judy can additionally obtain Alice’s secret key. Informally, we want that knowledge of Alice’s secret key does not help Judy in learning whether Alice sent any messages, even if Bob does not have Alice’s secret key and even if Bob cooperates with Judy by giving her his own secret key. This stronger flavor of Deniable Authentication was not considered before and is particularly relevant for Off-The-Record Group Messaging as it gives users stronger deniability guarantees.

Our main contribution is a scalable “MDRS-PKE” (Multi-Designated Receiver Signed Public Key Encryption) scheme—a technical formalization of Deniable Authentication that is particularly useful for secure messaging for its confidentiality guarantees—that provides this stronger deniability guarantee. At its core lie new MDVS (Multi-Designated Verifier Signature) and PKEBC (Public Key Encryption for Broadcast) scheme constructions: our MDVS is not only secure with respect to the new deniability notions, but it is also the first to be tightly secure under standard assumptions; our PKEBC—which is also of independent interest—is the first with ciphertext sizes and encryption and decryption times that grow only linearly in the number of receivers. This is a significant improvement upon the construction given by Maurer et al. (EUROCRYPT ’22), where ciphertext sizes and encryption and decryption times are quadratic in the number of receivers.

## 1 Introduction

*Motivation.* More than 3 billion people currently use messaging apps.<sup>3</sup> Naturally, there is a demand for *secure* messaging which guarantees, e.g., the secrecy

\* All of the work was done while author was at ETH Zurich.

<sup>3</sup> <https://www.businessofapps.com/data/messaging-app-market/>

of the transmitted contents, or the authenticity of senders. For point-to-point connections, combining standard cryptographic building blocks (like digital signature, public-key, and secret-key encryption schemes) may be sufficient. However, in particular for *group messaging* (in which groups of users communicate in a group chat), additional security properties are desirable. For instance, group members may want to be sure that all members receive the *same* messages (a property that, surprisingly, is not captured by traditional broadcast encryption definitions [8]).

Another security property that is generally desirable in messaging is *deniability*. Intuitively, it should be possible for a sender to deny having sent a message, or for a receiver to deny having received a particular message. Achieving deniability is even more challenging when considering that users may store copies of received (or even sent) messages on their communication device.

Here, we focus on a relatively mild (but still technically quite challenging) variant of deniability: “Off-The-Record” (OTR) messaging. Informally, with OTR security, received ciphertexts can be simulated, in the sense that it is easy to come with ciphertexts for arbitrary messages that *look* as if they had been sent by a particular sender. In this sense, OTR security guarantees that third parties cannot be convinced of group-internal interactions. Of course, even OTR is relatively difficult to achieve, and becomes even harder so in the group messaging setting.

*MDRS-PKE schemes.* When translating desirable properties of such group messaging protocols into suitable cryptographic primitives (with associated properties), we end up with “Multi-Designated Receiver Signed Public Key Encryption” (MDRS-PKE, [17]). Informally, these protocols function like signed versions of broadcast encryption schemes with additional integrity properties (that guarantee, e.g., that all receivers receive the same message). A little more formally, MDRS-PKE schemes work in a public-key infrastructure, and guarantee the following:

**Syntax:** A sender can prepare a single broadcast ciphertext  $c$  for a set  $\mathcal{R}$  of intended receivers. Any intended receiver in  $\mathcal{R}$  can decrypt  $c$  to retrieve the identity  $\text{pk}_S$  of the sender  $S$ , the encrypted message  $m$ , and the set  $\mathcal{R}$ .

**Consistency:** Not even a maliciously created  $c$  should decrypt to different sender identities, messages, or receiver sets for different intended receivers. Furthermore, if one receiver decrypts to  $(\text{pk}_S, m, \mathcal{R})$ , then all receivers in  $\mathcal{R}$  obtain the same  $(\text{pk}_S, m, \mathcal{R})$ .

**Unforgeability:** Nobody except  $S$  can produce a ciphertext that decrypts to sender identity  $\text{pk}_S$  for any receiver.

**Anonymity:**  $c$  does not reveal the sender  $S$  or the set  $\mathcal{R}$  of intended receivers (only its size  $|\mathcal{R}|$ ).

**Confidentiality:**  $c$  does not reveal the encrypted message (only its length  $|m|$ ).

**Off-The-Record:** Plausible-looking ciphertexts  $c$  can be simulated by any (subset of) intended receivers of that ciphertext. Intuitively, this guarantees that receivers cannot convince a third party of a received encrypted message.

MDRS-PKE is a complex primitive, and appears to require specific, case-tailored primitives to realize it. For instance, the combination of a *group* of designated receivers and the simulation properties required by OTR prevent the use of ordinary designated-verifier signatures (or even MACs) [6].

Fortunately, [17] show how to construct MDRS-PKE schemes from a combination of suitable variants of signature and broadcast encryption schemes. Specifically, they require the following:

- A type of signature scheme called “Multi-Designated Verifier Signature” (MDVS [5,6,13]) with suitable consistency, unforgeability, and OTR properties. (Here, “OTR” means that valid-looking signatures can be simulated by designated receivers.) State-of-the-art MDVS constructions [6] exist from algebraic assumptions (like the combination of Diffie-Hellman and Paillier-like assumptions), and also from generic primitives (like the combination of non-interactive key exchange (NIKE), non-interactive zero-knowledge (NIZK), and a few other standard primitives).
- A type of broadcast encryption scheme called “Public-Key Encryption for Broadcast” (PKEBC [17]) that essentially has all the properties of an MDRS-PKE scheme except for authenticity. PKEBC schemes can be instantiated from a combination of public-key encryption, NIZKs, and commitments.

*The current situation.* In summary, we do have tools that give meaningful security and privacy guarantees for group messaging even in face of corruptions. The current state of the art [6,17] leaves a few questions unanswered, however:

**Limited deniability guarantees.** The deniability (technically: OTR) guarantees given by the combination of [6,17] are limited to the case where the secret keys of honest senders remain secret. In particular, simulated ciphertexts are only proven to look plausible when the corresponding sender key is unknown. However, current deniability notions do not provide any guarantees if an honest sender is forced (or blackmailed) to give away its secret key, in which case the sender might not be able to plausibly deny having sent a message.

**Limited unforgeability guarantees.** The MDVS constructions and analyses from [6] show unforgeability only in a setting in which an adversary has no verification oracle. (Intuitively, in such designated-verifier settings, signatures are not publicly verifiable, and hence typically adversaries are given access to an explicit verification oracle [15,20].) This is undesirable, in particular because a constructive modeling of MDVS schemes [16] requires such a verification oracle. As a result, the resulting combined MDRS-PKE scheme from [6,17] suffers from a similarly weak unforgeability guarantee.<sup>4</sup>

---

<sup>4</sup> It should be noted that this shortcoming appears to have gone unnoticed. In particular, [17] explicitly define and assume MDVS schemes that are unforgeable in the presence of a verification oracle, while [6] simply do not prove this property about their MDVS schemes. Technically speaking, this means the transformation of [17] cannot be directly applied to the MDVS schemes from [6]. However, it is easy to see that the results from [17] carry over to “weakly unforgeable” (in the above sense) MDVS schemes, such that the result is simply a weakly unforgeable MDRS-PKE scheme.

**Limited scalability.** The combined MDRS-PKE construction of [6, 17] has ciphertexts whose sizes are *quadratic* in the number of receivers. This is clearly undesirable for large groups. Furthermore, while the generic transformation of [17] itself is tightly secure, i.e., gives security guarantees that do not incur a loss in the number of parties or ciphertexts, the underlying primitives from [6, 17] are not known to be. In particular, the (known) security guarantees of the final scheme degrade in the number of ciphertexts and users.

**Gaps in some proofs.** Unfortunately, some of the proofs in [6] appear incomplete. (See Section C in the Appendix for details.)

*Our contribution.* In this work, we construct a MDRS-PKE scheme that

- enjoys strong deniability guarantees (i.e. a strong OTR notion that takes into account leaked sender secret keys),
- likewise enjoys strong unforgeability properties (that take into account adversaries with a verification oracle),
- is scalable, in the sense that ciphertext sizes, encryption and decryption times are linear in the number of receivers, and we can prove it tightly secure based on primitives for which tightly secure instantiations are known.

Like [17], our MDRS-PKE scheme is based upon suitable MDVS and PKEBC schemes. In fact, we use the same generic MDRS-PKE construction as [17], but for more secure and more efficient MDVS and PKEBC schemes (that we also provide). In particular, we provide

- a conceptually simple MDVS scheme that achieves strong OTR and strong unforgeability guarantees (as explained above),
- a PKEBC scheme for which ciphertext sizes, and both encryption and decryption times only grow linearly with the number of receivers.

Both of these schemes can be proven tightly secure from primitives that have tightly secure instantiations from standard computational assumptions. In particular, unlike [6], we avoid the use of non-interactive key exchange, a primitive which is known to be difficult to prove tightly secure [2, 12].

## 2 Technical Overview

We now give an overview of the techniques used to construct our MDRS-PKE scheme. As aforementioned, our scheme is tightly secure under adaptive corruptions and satisfies the new (stronger) OTR notion considered in this paper. The main building blocks of our construction are: 1. a new MDVS scheme construction satisfying (the MDVS analogous of) the new OTR security notion which is tightly secure under adaptive corruptions; and 2. a new PKEBC scheme construction with linear-size ciphertexts, and linear-time encryption and decryption which is also tightly secure under adaptive corruptions. By following (a straightforward generalization of) the transformation given in [17] we then obtain the intended MDRS-PKE scheme. It is worth noting that, since the MDRS-PKE construction

given in [17] uses the PKEBC scheme to encrypt a message whose size is already linear in the number of receivers, it is not sufficient for the underlying PKEBC scheme to have ciphertext sizes, encryption and decryption times that grow linearly with the number of receivers *times* the size of the message: it is necessary for the PKEBC’s ciphertext sizes, encryption and decryption times to grow linearly with the number of receivers *plus* the size of the message. This is exactly what we achieve: when instantiated with our new MDVS and PKEBC constructions, the MDRS-PKE construction given in [17] yields the first (MDRS-PKE) scheme that satisfies the new stronger OTR notion, that has ciphertext size, encryption and decryption times that grow linearly with the number of receivers, and that is tightly secure under adaptive corruptions.

## 2.1 MDVS Construction

We now give an overview of our MDVS scheme construction. As a first step we consider the case of a single verifier and show how to construct a Designated Verifier Signature (DVS) scheme. This already conveys the main technical ideas of our construction. Then we discuss how to generalize the DVS to the case of multiple verifiers (MDVS), and, finally, we explain how to achieve tight security under adaptive corruptions. The building blocks of all our (M)DVS constructions are an IND-CPA secure PKE scheme, a One-Way Function (OWF)  $F$  and a Simulation-Sound (SS) NIZK.

*The DVS scheme.* Our signature scheme is of the following form: the public parameters  $\mathbf{pp}$  consist of a public key  $\mathbf{pk}$  of the PKE scheme, and a *Common Reference String*  $\mathbf{crs}$  of the NIZK argument system. The secret signing key  $\mathbf{ssk}$  is a pre-image  $x_S$  of the OWF  $F$  and the signer’s public key  $\mathbf{spk}$  is the corresponding image (i.e.  $\mathbf{spk} = y_S = F(x_S)$ ). A verifier’s key-pair is similar, except that it additionally includes a PKE key pair  $(\mathbf{pk}_V, \mathbf{sk}_V)$ : the verifier’s secret key  $\mathbf{vsk}$  consists of a pre-image  $x_V$  of  $F$  together with the PKE secret key  $\mathbf{sk}_V$ ; the verifier’s public key  $\mathbf{vpk}$  are the corresponding public keys, i.e.  $\mathbf{vpk} = (\mathbf{pk}_V, y_V := F(x_V))$ . To sign a message  $m$  (using  $\mathbf{ssk} = x_S$ , and  $\mathbf{vpk} = (\mathbf{pk}_V, y_V)$ ), we first generate two ciphertexts,  $c$  and  $c_{\mathbf{pp}}$ :  $c$  encrypts the bit 1 under the verifier’s public key  $\mathbf{pk}_V$  (the role of this will be clear soon);  $c_{\mathbf{pp}}$  encrypts the tuple  $(m, 1, \mathbf{ssk})$  under the public key  $\mathbf{pk}$  included in the public parameters  $\mathbf{pp}$ . Finally, we generate a NIZK proof  $\pi$  that binds the ciphertexts together:  $\pi$  proves that both  $c_{\mathbf{pp}}$  and  $c$  are well-formed and encrypt the same bit  $b$ , and that if  $b = 1$  then  $c_{\mathbf{pp}}$  encrypts a pre-image (under  $F$ ) of either  $y_S$  or  $y_V$ . The signature  $\sigma$  then consists of the tuple  $(c_{\mathbf{pp}}, c, \pi)$ . To verify a signature the receiver first verifies the NIZK proof  $\pi$  and then decrypts ciphertext  $c$  using its PKE secret key  $\mathbf{sk}_V$ ; the signature is valid if  $\pi$  is a valid NIZK proof and the decryption of  $c$  is 1.

Simulating a signature works as follows: 1. for the case of a dishonest verifier, to simulate a signature one proceeds just like an honest signer would to generate a signature, the only difference being that  $c_{\mathbf{pp}}$ , instead of encrypting  $x_S$ —the pre-image of the signer’s public key—encrypts  $x_V$ —the pre-image of the verifier’s public key; 2. if the verifier is honest, one forges a signature by having  $c$  be an

encryption of 0 under the verifier’s public PKE key  $\text{pk}_V$ ,  $c_{\text{pp}}$  be an encryption of the triple  $(m, 0, 0)$ , and  $\pi$  be a NIZK proof. Note that, thanks to the NIZK relation we consider, in both cases one can compute a valid NIZK proof  $\pi$ : in the first case this is possible because  $c_{\text{pp}}$  encrypts a pre-image of the verifier’s secret key; for the latter case this is possible because  $c$  is an encryption of 0.

To understand why the DVS scheme sketched above is unforgeable note first that if both the sender and the verifier are honest, by the one-wayness of  $F$  the adversary does not know a pre-image of neither  $F(x_S)$  nor  $F(x_V)$ . On a high level the proof proceeds as follows: we begin by changing both the public parameter’s  $\text{crs}$  and each signature’s NIZK proof by simulated ones. We, next, further modify the signatures the adversary sees by making  $c_{\text{pp}}$  be an encryption of a “0” string—possible by the IND-CPA security of the underlying PKE scheme. Note that at this point all the adversary sees is independent of both  $\text{ssk} = x_S$  and  $\text{vsk} = x_V$ .<sup>5</sup> Now suppose the adversary manages to come up with a forgery  $(c_{\text{pp}}^*, c^*, \pi^*)$  corresponding to some message  $m^*$  whose signature it has never seen: if the forgery is valid then on one hand  $c^*$  is encryption of bit 1 and on the other hand  $\pi^*$  is a valid NIZK proof; by (simulation) soundness this means that  $c_{\text{pp}}^*$  encrypts a pre-image of either  $y_S$  or  $y_V$ . However, at this point we can use the PKE secret key corresponding to the public parameter’s public key to extract the pre-image, contradicting the one-wayness of  $F$ .

Understanding why the scheme sketched above satisfies the (stronger) OTR property is more involved (and refer the reader to the full proof of Theorem 6 for details). For simplicity, below we consider a weaker OTR notion—one where the adversary is not given access to a signature verification oracle: 1. If the verifier is dishonest the only differences between real and simulated signatures are that in the first case  $c_{\text{pp}}$  encrypts  $x_S$  and the NIZK proof  $\pi$  is generated using  $x_S$  as (part of the) witness, whereas in the latter case  $c_{\text{pp}}$  encrypts  $x_V$  and  $\pi$  is generated using  $x_V$ . If an adversary were able to distinguish real signatures from simulated ones then it would be either breaking the IND-CPA security of the underlying PKE scheme, or the Zero-Knowledge security of the NIZK (or both). 2. If the verifier is honest the differences between real signatures and simulated ones are that in the first case  $c_{\text{pp}}$  encrypts  $x_S$ ,  $c$  is an encryption of 1 and  $\pi$  is generated using  $x_S$ , while in a simulated signature  $c_{\text{pp}}$  encrypts a “0” string,  $c$  is an encryption of 0 and  $\pi$  is no longer generated using a pre-image of neither  $y_S$  nor  $y_V$ . So, if an adversary were able to distinguish real and simulated signatures then it could break the IND-CPA security of the underlying PKE scheme—since it could distinguish either the  $c_{\text{pp}}$  or the  $c$  ciphertexts—or could break the Zero-Knowledge of the NIZK.

*Generalizing for multiple verifiers.* We now discuss how to extend the previous construction to the case of multiple designated verifiers. The main difference is that we additionally need to guarantee consistency—meaning that either all honest verifiers accept a signature, or they all reject.

<sup>5</sup> Here, independent is in the sense that all the adversary sees only depends on  $y_S := F(x_S)$  and  $y_V := F(x_V)$ , but not on any pre-image of  $y_S$  or  $y_V$ .

Signatures in our MDVS construction consist of a vector of ciphertexts  $\vec{c} = (c_1, \dots, c_n)$  (one per receiver) and a ciphertext  $c_{\text{pp}}$ . Each ciphertext  $c_i$  is the encryption of a bit  $b_i$  under the  $i$ -th receiver’s public key  $\text{pk}_{V_i}$ , and the ciphertext  $c_{\text{pp}}$  is an encryption of the tuple  $(m, b_{\text{global}}, \vec{\alpha} = (\alpha_1, \dots, \alpha_n))$ , where  $\alpha_i = (b_i, x_i)$ , under the public parameter’s public key  $\text{pk}$ . Similarly to the DVS construction, signatures also contain a NIZK proof  $\pi$  that not only ensures ciphertexts are well-formed and signatures are unforgeable, but also consistency. In particular,  $\pi$  proves: 1. all ciphertexts in  $\vec{c}$  and ciphertext  $c_{\text{pp}}$  are well-formed—in particular each ciphertext  $c_i$  of  $\vec{c}$  encrypts the bit  $b_i$  that is in the  $\alpha_i$  encrypted in  $c_{\text{pp}}$ ; 2. for each verifier, say the  $i$ -th, if  $b_i = 1$  then the  $\alpha_i$  encrypted in  $c_{\text{pp}}$  contains a pre-image of either  $y_S$ —the signer’s public key—or  $y_{V_i}$ —the  $i$ -th verifier’s public key—under  $F$  (this guarantees unforgeability); and 3. for each  $i$ -th verifier, if the value  $x_i$  in  $\alpha_i$  that is encrypted under  $c_{\text{pp}}$  is not a pre-image of this verifier’s public key  $y_{V_i}$  then  $b_i = b_{\text{global}}$  (this guarantees consistency). Note that, if the verification of the NIZK proof is deterministic, the NIZK’s soundness implies that if two verifiers disagree on a signature’s validity, one of them is dishonest.

*Achieving tight security under adaptive corruptions.* While the MDVS construction above already satisfies correctness, consistency, unforgeability and OTR, we do not know how to prove it is tightly secure under adaptive corruptions. Our problem is that we do not know how a reduction could know in advance which parties the adversary will corrupt (and thus ask for their secret keys) and which ones it will not. Suppose for example we are reducing an adversary from breaking some security property of the MDVS construction to breaking the IND-CPA game of the underlying PKE scheme, and in particular consider a reduction that simply guesses whether the adversary will corrupt a party  $P_i$ : on one hand, if the reduction guesses incorrectly that  $P_i$  will be corrupted then it is not taking advantage of the adversary to win the underlying IND-CPA game; on the other hand, if the reduction incorrectly guesses  $P_i$  will not be corrupted—in which case it would set  $P_i$ ’s public key to be one output by the underlying IND-CPA game—then we do not know how the reduction could handle a query for the secret key of  $P_i$ —and so the reduction would again not be taking advantage of the adversary to win the underlying IND-CPA game. So although one could resort to this guessing technique to prove the security of the MDVS scheme under adaptive corruptions (via a hybrid argument), this leads to a reduction loss that grows linearly with the number of parties.

To void this reduction loss we follow the “two-key” technique already used in the context of tightly secure public-key encryption [1]. In the new scheme, and at a high level, the public key of each party  $P_i$  is a pair of public keys—say  $(\text{pk}_0, \text{pk}_1)$ —from the previous scheme, and its secret key consists of a bit  $b$ —picked uniformly at random—and the secret key  $\text{sk}_b$  corresponding to  $\text{pk}_b$ . Signatures then consist of  $c_{\text{pp}}$  as before, a vector of ciphertexts that includes two ciphertexts per verifier—one under each of the verifier’s public keys—and the NIZK proof  $\pi$ —which now proves that  $c_{\text{pp}}$  encrypts a pre-image of one of the public keys of a party (rather than a single one as before). This technique allows to come up with tight security reductions to the underlying building blocks: having the

two keys allows, on one hand, to embed challenges in the part of the public key whose corresponding secret key is “forgotten”, i.e.  $\mathbf{pk}_{1-b}$ , where  $b$  is the bit in the party’s secret key, and on the other hand to handle any possible queries the adversary may make, including ones where the party’s secret key is leaked.

## 2.2 PKEBC Construction

We now give a high level overview of our PKEBC scheme’s construction. We first explain how to achieve linear sized ciphertexts and linear time encryption (in the number of receivers), and then move towards making decryption time also linear. (We note that the ciphertext size and both the encryption and decryption times of the only prior PKEBC scheme construction (see [17]) all grow quadratically in the number of receivers.) Since the technique we use to obtain tight security reductions under adaptive corruptions is the same one we used in the MDVS construction, we do not include it in this overview.

As building blocks, we assume an IND-CPA and IK-CPA secure PKE scheme, a Simulation-Sound NIZK and a (one-time) IND-CPA secure Symmetric Encryption (SKE) scheme. The public parameters of our PKEBC schemes are the same as for the MDVS construction—comprising a public key of a PKE scheme and a  $\mathbf{crs}$  for a NIZK, i.e.  $\mathbf{pp} = (\mathbf{pk}, \mathbf{crs})$ —and in the two constructions discussed below a PKEBC key-pair is simply a key-pair of the underlying PKE scheme.

*Achieving linear ciphertext size and encryption time.* As we now explain, the main idea to achieve linear ciphertext sizes and encryption time (in the number of receivers) is to use hybrid encryption.

To encrypt a message  $m$  to a vector of receiver public keys  $\vec{v} = (\mathbf{pk}_1, \dots, \mathbf{pk}_n)$  we first encrypt  $(\vec{v}, m)$  under the public parameters’ public key; let  $c_{\mathbf{pp}}$  denote the resulting ciphertext and  $r_{\mathbf{pp}}$  the sequence of random bits used for this encryption. Next we generate a symmetric key  $k$  for the SKE scheme and for each receiver public key  $\mathbf{pk}_i$  in  $\vec{v}$  we encrypt  $k$  under  $\mathbf{pk}_i$ , resulting in a vector of ciphertexts  $(c_1, \dots, c_n)$ . Then we use  $k$  to encrypt not only  $\vec{v}$  and  $m$ , but also  $r_{\mathbf{pp}}$ ; let  $c_{\mathbf{sym}}$  denote the resulting (symmetric) ciphertext. (Having  $c_{\mathbf{sym}}$  encrypt  $\vec{v}$ ,  $m$  and  $r_{\mathbf{pp}}$  allows receivers to confirm they obtained the correct vector of receivers and message: since the public parameter’s public key is honestly sampled,  $c_{\mathbf{pp}}$  is a commitment to  $(\vec{v}, m)$ , and since  $c_{\mathbf{sym}}$  also encrypts  $r_{\mathbf{pp}}$ , a receiver can simply recompute  $c_{\mathbf{pp}}$ ; as we will see, this is key to guaranteeing correctness, robustness and consistency.) Finally, we create a NIZK proof  $\pi$  showing that: 1.  $c_{\mathbf{pp}}$  is an encryption of  $(\vec{v}, m)$  under the public parameters’ public key using  $r_{\mathbf{pp}}$  as the sequence of random encryption bits; 2. the symmetric key  $k$  was correctly sampled; 3.  $c_{\mathbf{sym}}$  is an encryption under  $k$  of  $(r_{\mathbf{pp}}, \vec{v}, m)$ ; and 4. for each ciphertext  $c_i$  of  $\vec{c}$ ,  $c_i$  is an encryption of  $k$  under the  $i$ -th public key  $\mathbf{pk}_i$  of  $\vec{v}$ . The final ciphertext is then the quadruple  $c = (c_{\mathbf{pp}}, \vec{c}, c_{\mathbf{sym}}, \pi)$ . To decrypt a receiver first checks if  $\pi$  is a valid NIZK proof; if  $\pi$  is valid the receiver then starts trying to decrypt each ciphertext  $c_i \in \vec{c}$ ; for each symmetric key  $k'$  the receiver obtains from successfully decrypting a ciphertext  $c_i$ , the receiver tries decrypting  $c_{\mathbf{sym}}$ . If the decryption of  $c_{\mathbf{sym}}$  is successful, returning a triple  $(r_{\mathbf{pp}}, \vec{v}, m)$ , the receiver

checks if  $c_{\text{pp}}$  indeed encrypts  $(\vec{v}, m)$  under the public parameters’ public key using  $r_{\text{pp}}$  as the random encryption coins, and if it does the receiver outputs  $(\vec{v}, m)$  as the result of decryption. If it does not (or any of the decryption attempts failed) the receiver moves on to the next ciphertext  $c_j$  of  $\vec{c}$ , or returns the special error symbol  $\perp$  if there are no more ciphertexts.

It is easy to see that for a vector of receivers  $\vec{v}$  and message  $m$  both the ciphertext size and the encryption time of the scheme are  $O(|\vec{v}| + |m|)$ , exactly as we needed. Unfortunately, the scheme *does not* achieve linear time decryption: in the worst case the decryption of each ciphertext  $c_i \in \vec{c}$  outputs a valid looking symmetric key  $k'^6$ , the decryption of  $c_{\text{sym}}$  is successful—which, given the size of  $c_{\text{sym}}$  is linear in the number of receivers, already takes time linear in the number of receivers—but then the triple  $(r_{\text{pp}'}, \vec{v}', m')$  resulting from  $c_{\text{sym}}$ ’s decryption does not match  $c_{\text{pp}}$ , i.e.  $c_{\text{pp}}$  is not the encryption of  $(\vec{v}', m')$  under the public key of the public parameters, and using  $r_{\text{pp}'}$  as the random encryption coins. Given the number of ciphertexts of  $\vec{c}$  is linear in the number of receivers, the time to decrypt then grows *quadratically* in the number of receivers.

*Achieving linear decryption time.* To achieve linear time decryption receivers need a fast way of checking if any particular ciphertext  $c_j \in \vec{c}$  is really meant for them without having to decrypt  $c_{\text{sym}}$ , as this already takes linear time in the number of receivers. A first idea is adding, for each receiver, an encryption of a long enough 0 bitstring (and appropriately modifying the NIZK relation): to decrypt, a receiver would then first check if the decryption of this new ciphertext would output back the expected 0 bitstring, and if not the receiver would not have to attempt decrypting the (linear sized)  $c_{\text{sym}}$  ciphertext. Unfortunately, this approach only works for honestly generated ciphertexts. For instance, consider two key-pairs  $(\text{pk}, \text{sk}), (\text{pk}', \text{sk}')$  of some arbitrary PKE scheme with  $\text{pk} \neq \text{pk}'$ : one cannot assume that an adversarially created encryption of a 0 bitstring under  $\text{pk}$  does not decrypt, under the non-matching secret key  $\text{sk}'$ , to the same 0 bitstring (and, more generally, to any particular value). This means that a dishonest sender could potentially come up with “malformed” ciphertexts that would pass this first check, thus making a receiver have to decrypt the (large)  $c_{\text{sym}}$  ciphertext and then recompute  $c_{\text{pp}}$  to ensure consistency.

The way our scheme achieves linear time decryption is by pairing each ciphertext  $c_i \in \vec{c}$  with: 1. a commitment to the  $i$ -th receiver’s public key  $\text{pk}_i$ ; and 2. a ciphertext that encrypts, under  $\text{pk}_i$ , the random coins used to generate the commitment. More concretely, in our scheme there are three ciphertexts per receiver, i.e.  $\vec{c} = (c_1, \dots, c_n)$  with  $c_i = (c_{i,0}, c_{i,1}, c_{i,2})$ , where:  $c_{i,0}$  is an encryption, under the public parameter’s public key, of the  $i$ -th receiver’s public key  $\text{pk}_i$  using some sequence of random bits  $r_{i,0}$ ;  $c_{i,1}$  is an encryption, under  $\text{pk}_i$ , of the random coins  $r_{i,0}$ ; and  $c_{i,2}$  is an encryption of the SKE key  $k$  used to encrypt  $c_{\text{sym}}$ . As one might note, by appropriately modifying the NIZK statement, we can ensure that receivers no longer need to recompute  $c_{\text{pp}}$  to confirm they obtained

---

<sup>6</sup> For an arbitrary PKE scheme a receiver cannot *a priori* tell whether a given ciphertext is intended for itself.

the correct pair  $(\vec{v} = (\mathbf{pk}_1, \dots, \mathbf{pk}_n), m)$  from the decryption of  $c_{\text{sym}}$ : first, note that the correctness of the underlying PKE scheme together with the soundness of the NIZK (for the modified NIZK statement) guarantee that ciphertext  $c_{j,0}$  of each triple  $c_j = (c_{j,0}, c_{j,1}, c_{j,2})$  of  $\vec{c}$  binds the triple to a single receiver public key  $\mathbf{pk}_j$ ; second, the PKE scheme's correctness with the NIZK's soundness further imply that ciphertext  $c_{j,2}$  of every triple is an encryption of the same symmetric key  $k$  under the public key  $\mathbf{pk}_j$  bound to the triple; third, the SKE's (perfect) correctness again with the NIZK's soundness imply that the decryption of  $c_{\text{sym}}$  using the aforementioned key  $k$  yields the same pair  $(\vec{v} = (\mathbf{pk}_1, \dots, \mathbf{pk}_n), m)$ , where for each  $i \in \{1, \dots, n\}$ , the triple  $c_i \in \vec{c}$  is bound to the (corresponding) public key  $\mathbf{pk}_i \in \vec{v}$ . Since, as explained above, receivers need not recompute  $c_{\text{pp}}$ , in the new scheme  $c_{\text{sym}}$  no longer encrypts the random coins  $r_{\text{pp}}$ . Furthermore, as each receiver's public key  $\mathbf{pk}_i$  is already encrypted under the public parameter's public key in  $c_{i,0}$ ,  $c_{\text{pp}}$  no longer needs to encrypt vector  $\vec{v}$ ; in the new scheme  $c_{\text{pp}}$  encrypts only the message  $m$ .

### 3 Preliminaries

We denote the arity of a vector  $\vec{x}$  by  $|\vec{x}|$  and its  $i$ -th element by  $x_i$ . We write  $\alpha \in \vec{x}$  to denote  $\exists i \in \{1, \dots, |\vec{x}|\}$  with  $\alpha = x_i$ . We write  $\text{Set}(\vec{x})$  to denote the set induced by vector  $\vec{x}$ , i.e.  $\text{Set}(\vec{x}) := \{x_i \mid x_i \in \vec{x}\}$ .

Throughout the paper we frequently use vectors. We use upper case letters to denote vectors of parties, and lower case letters to denote vectors of artifacts such as public keys, sequences of random coins, etc. Moreover, we use the convention that if  $\vec{V}$  is a vector of parties, then  $\vec{v}$  denotes  $\vec{V}$ 's corresponding vector of public keys. For example, for a vector of parties  $\vec{V} := (\text{Bob}, \text{Charlie})$ ,  $\vec{v} := (\mathbf{pk}_{\text{Bob}}, \mathbf{pk}_{\text{Charlie}})$  is  $\vec{V}$ 's corresponding vector of public keys. In particular,  $V_1$  is Bob and  $v_1$  is Bob's public key  $\mathbf{pk}_{\text{Bob}}$ , and  $V_2$  is Charlie and  $v_2$  is Charlie's public key  $\mathbf{pk}_{\text{Charlie}}$ . More generally, for a vector of parties  $\vec{V}$  with corresponding vector of public keys  $\vec{v}$ ,  $V_i$ 's public key is  $v_i$ , for  $i \in \{1, \dots, |\vec{V}|\}$ .

### 4 Multi-Designated Verifier Signature Schemes with Enhanced Off-The-Record Security

An MDVS scheme  $\Pi$  is a 6-tuple of Probabilistic Polynomial Time Algorithms (PPTs)  $\Pi = (S, G_S, G_V, \text{Sig}, \text{Vfy}, \text{Forge})$ , where:

- $S$ : on input  $1^k$ , generates public parameters  $\mathbf{pp}$ ;
- $G_S$ : on input  $\mathbf{pp}$ , generates a signer key-pair  $(\mathbf{spk}, \mathbf{ssk})$ ;
- $G_V$ : on input  $\mathbf{pp}$ , generates a verifier key-pair  $(\mathbf{vpk}, \mathbf{vsk})$ ;
- $\text{Sig}$ : on input  $(\mathbf{pp}, \mathbf{ssk}, \vec{v}, m)$ , where  $\mathbf{ssk}$  is the signer's secret key,  $\vec{v}$  is the vector of public verifier keys of the designated verifiers and  $m$  is the message, generates a signature  $\sigma$ ;

- *Vfy*: on input  $(\text{pp}, \text{spk}, \text{vsk}, \vec{v}, m, \sigma)$ , where  $\text{vsk}$  is a verifier’s secret key, *Vfy* checks if  $\sigma$  is a valid signature on message  $m$  with respect to signer’s public key  $\text{spk}$  and vector of verifier public keys  $\vec{v}$ ;
- *Forge*: on input  $(\text{pp}, \text{spk}, \vec{v}, m, \vec{s})$ , where  $\text{spk}$  is the signer’s public key,  $\vec{v}$  is the vector of the designated verifiers’ public keys,  $\vec{s}$  is a vector of designated verifiers’ secret keys—with  $|\vec{s}| = |\vec{v}|$  and where for  $i \in \{1, \dots, |\vec{v}|\}$ , either  $s_i = \perp$  or  $s_i$  is the secret key corresponding to the  $i$ -th public key of  $\vec{v}$ , i.e.  $v_i$ —and  $m$  is the message, generates a forged signature  $\sigma$ .

In this section we introduce a new (stronger) Off-The-Record security notion for MDVS schemes capturing the setting where the signer’s secret key can leak (Definition 4) and give a new construction satisfying this stronger notion.

#### 4.1 Security Notions

Let  $\Pi = (S, G_S, G_V, \text{Sig}, \text{Vfy}, \text{Forge})$  be an MDVS scheme. The MDVS security games ahead have an implicitly defined security parameter  $k$ , and provide adversaries with access to the following oracles:

**Public Parameter Generation Oracle:**  $\mathcal{O}_{PP}$

1. On the first call to  $\mathcal{O}_{PP}$ , compute  $\text{pp} \leftarrow S(1^k)$ ; output  $\text{pp}$ ;
2. On subsequent calls, simply output  $\text{pp}$ .

**Signer Key-Pair Generation Oracle:**  $\mathcal{O}_{SK}(A_i)$

1. On the first call to  $\mathcal{O}_{SK}$  on input  $A_i$ , compute  $(\text{spk}_i, \text{ssk}_i) \leftarrow G_S(\text{pp})$ , and output  $(\text{spk}_i, \text{ssk}_i)$ ;
2. On subsequent calls, simply output  $(\text{spk}_i, \text{ssk}_i)$ .

**Verifier Key-Pair Generation Oracle:**  $\mathcal{O}_{VK}(B_j)$

1. Analogous to the Signer Key-Pair Generation Oracle.

**Signer Public-Key Oracle:**  $\mathcal{O}_{SPK}(A_i)$

1.  $(\text{spk}_i, \text{ssk}_i) \leftarrow \mathcal{O}_{SK}(A_i)$ ; output  $\text{spk}_i$ .

**Verifier Public-Key Oracle:**  $\mathcal{O}_{VPK}(B_j)$

1. Analogous to the Signer Public-Key Oracle.

**Signing Oracle:**  $\mathcal{O}_S(A_i, \vec{V}, m)$

1.  $(\text{spk}_i, \text{ssk}_i) \leftarrow \mathcal{O}_{SK}(A_i)$ ;
2.  $\vec{v} = (\mathcal{O}_{VPK}(V_1), \dots, \mathcal{O}_{VPK}(V_{|\vec{v}|}))$ ;
3. Output  $\sigma \leftarrow \text{Sig}_{\text{pp}}(\text{ssk}_i, \vec{v}, m)$ .

**Verification Oracle:**  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma)$

1.  $\text{spk}_i \leftarrow \mathcal{O}_{SPK}(A_i)$ ;
2.  $\vec{v} = (\mathcal{O}_{VPK}(V_1), \dots, \mathcal{O}_{VPK}(V_{|\vec{v}|}))$ ;
3.  $(\text{vpk}_j, \text{vsk}_j) \leftarrow \mathcal{O}_{VK}(B_j)$ ;
4. Output  $d \leftarrow \text{Vfy}_{\text{pp}}(\text{spk}_i, \text{vsk}_j, \vec{v}, m, \sigma)$ , where  $d \in \{0, 1\}$ .

**Definition 1 (Correctness).** *Game system  $\mathbf{G}^{\text{Corr}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$ .  $\mathbf{A}$  wins the game if there are two queries  $q_S$  and  $q_V$  to  $\mathcal{O}_S$  and  $\mathcal{O}_V$ , respectively, where  $q_S$  has input  $(A_i, \vec{V}, m)$  and  $q_V$  has input  $(A_i', B_j, \vec{V}', m', \sigma)$ , satisfying  $(A_i, \vec{V}, m) =$*

$(A_i', \vec{V}', m')$ ,  $B_j \in \vec{V}$ , the input  $\sigma$  in  $q_V$  is the output of the oracle  $\mathcal{O}_S$  on query  $q_S$ , and the output of the oracle  $\mathcal{O}_V$  on the query  $q_V$  is 0. The advantage of  $\mathbf{A}$  in winning the Correctness game, denoted  $\text{Adv}^{\text{Corr}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Corr}}$  as described above.

We say an adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_V, q_S, q_V)$ -Correctness of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$  on at most  $n_V$  different verifiers, makes at most  $q_S$  and  $q_V$  queries to  $\mathcal{O}_S$  and  $\mathcal{O}_V$ , respectively, and satisfies  $\text{Adv}^{\text{Corr}}(\mathbf{A}) \geq \varepsilon$ .

**Definition 2 (Consistency).** Game  $\mathbf{G}^{\text{Cons}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$ . We say that  $\mathbf{A}$  wins the game if it queries  $\mathcal{O}_V$  on inputs  $(A_i, B_j, \vec{V}, m, \sigma)$  and  $(A_i', B_j', \vec{V}', m', \sigma')$  with  $(A_i, \vec{V}, m, \sigma) = (A_i', \vec{V}', m', \sigma')$  and where  $\{B_j, B_j'\} \subseteq \vec{V}$ , the outputs of the two queries differ, and there is no  $\mathcal{O}_{VK}$  query on either  $B_j$  or  $B_j'$ . The advantage of  $\mathbf{A}$  in winning the Consistency game, denoted  $\text{Adv}^{\text{Cons}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Cons}}$  as described above.

An adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_V, q_V)$ -Consistency of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$  on at most  $n_V$  different verifiers, makes at most  $q_V$  queries to  $\mathcal{O}_V$  and satisfies  $\text{Adv}^{\text{Cons}}(\mathbf{A}) \geq \varepsilon$ .

**Definition 3 (Unforgeability).** Game system  $\mathbf{G}^{\text{Unforg}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$ .  $\mathbf{A}$  wins if it makes a query  $\mathcal{O}_V(A_i^*, B_j^*, \vec{V}^*, m^*, \sigma^*)$  with  $B_j^* \in \vec{V}^*$  that outputs 1, for every query  $\mathcal{O}_S(A_i', \vec{V}', m')$ ,  $(A_i^*, \vec{V}^*, m^*) \neq (A_i', \vec{V}', m')$ , and there is no  $\mathcal{O}_{SK}$  query on  $A_i^*$  nor  $\mathcal{O}_{VK}$  query on  $B_j^*$ . The advantage of  $\mathbf{A}$  in winning the Unforgeability game is the probability that  $\mathbf{A}$  wins  $\mathbf{G}^{\text{Unforg}}$ , and is denoted  $\text{Adv}^{\text{Unforg}}(\mathbf{A})$ .

An adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_S, n_V, q_S, q_V)$ -Unforgeability of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$  on at most  $n_S$  different signers,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_S$  and  $\mathcal{O}_V$  on at most  $n_V$  different verifiers, makes at most  $q_S$  and  $q_V$  queries to  $\mathcal{O}_S$  and  $\mathcal{O}_V$ , respectively, and satisfies  $\text{Adv}^{\text{Unforg}}(\mathbf{A}) \geq \varepsilon$ .

**4.1.1 New Off-The-Record Security Notion.** We now present the new enhanced off-the-record security notion for MDVS schemes. As already mentioned, the main difference between our new notion and the existing one (see [6, 17]) is that in our new notion the adversary can query for the secret key of any sender (and still win the game). This is reflected in Definition 4 in that there is no restriction on which signer secret keys an adversary may query.

The off-the-record security notion defines two game systems,  $\mathbf{G}_0^{\text{OTR}}$  and  $\mathbf{G}_1^{\text{OTR}}$ , which provide adversaries with access to an additional oracle  $\mathcal{O}_{\text{Challenge}}$  whose behavior varies depending on the underlying game system:

**Challenge Oracle:**  $\mathcal{O}_{\text{Challenge}}(\text{type} \in \{\text{sig}, \text{sim}\}, A_i, \vec{V}, m, \mathcal{C})$

For game system  $\mathbf{G}_b^{\text{OTR}}$ , the oracle behaves as follows:

1.  $(\text{spk}_i, \text{ssk}_i) \leftarrow \mathcal{O}_{SK}(A_i)$ ;

2. Let  $\vec{v} = (v_1, \dots, v_{|\vec{V}|})$  and  $\vec{s} = (s_1, \dots, s_{|\vec{V}|})$ , where, for  $i \in \{1, \dots, |\vec{V}|\}$ :
 
$$- (v_i, s_i) = \begin{cases} \mathcal{O}_{VK}(V_i) & \text{if } V_i \in \mathcal{C} \\ (\mathcal{O}_{VPK}(V_i), \perp) & \text{otherwise;} \end{cases}$$
3.  $(\sigma_0, \sigma_1) \leftarrow (\Pi.\text{Sig}_{\text{pp}}(\text{ssk}_i, \vec{v}, m), \Pi.\text{Forge}_{\text{pp}}(\text{spk}_i, \vec{v}, m, \vec{s}))$ ;
4. If  $\mathbf{b} = 0$ , output  $\sigma_0$  if  $\text{type} = \text{sig}$  and  $\sigma_1$  if  $\text{type} = \text{sim}$ ; otherwise, if  $\mathbf{b} = 1$ , output  $\sigma_1$ .

**Definition 4 (Off-The-Record).** For  $\mathbf{b} \in \{0, 1\}$ , game  $\mathbf{G}_{\mathbf{b}}^{\text{OTR}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_V$  and  $\mathcal{O}_{\text{Challenge}}$ . We say that  $\mathbf{A}$  wins the game if it outputs a guess bit  $b'$  with  $b' = \mathbf{b}$ , and for every query  $\mathcal{O}_{\text{Challenge}}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$ : 1.  $\mathcal{C} \subseteq \text{Set}(\vec{V})$ ; 2. there is no query  $\mathcal{O}_{VK}(B_j)$  with  $B_j \in \text{Set}(\vec{V}) \setminus \mathcal{C}$ ; 3. letting  $\sigma$  be the output of the  $\mathcal{O}_{\text{Challenge}}$  query above, there is no query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma)$  with  $B_j \in \vec{V}$ . The advantage of  $\mathbf{A}$  in winning the Off-The-Record security game is

$$\text{Adv}^{\text{OTR}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{\text{OTR}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{OTR}} = \text{win}] - 1 \right|.$$

An adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_V, d_S, q_S, q_V)$ -Off-The-Record security of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{VPK}$ ,  $\mathcal{O}_V$  and  $\mathcal{O}_{\text{Challenge}}$  on at most  $n_V$  different verifiers, makes at most  $q_S$  and  $q_V$  queries to  $\mathcal{O}_{\text{Challenge}}$  and  $\mathcal{O}_V$ , respectively, with the sum of the verifier vectors' lengths input to  $\mathcal{O}_{\text{Challenge}}$  being at most  $d_S$ , and satisfies  $\text{Adv}^{\text{OTR}}(\mathbf{A}) \geq \varepsilon$ . We say that  $\Pi$  is

$$(\varepsilon_{\text{Corr}}, \varepsilon_{\text{Cons}}, \varepsilon_{\text{Unforg}}, \varepsilon_{\text{OTR}}, t, n_S, n_V, d_S, q_S, q_V)\text{-secure}$$

if there is no adversary  $\mathbf{A}$  that: 1.  $(\varepsilon_{\text{Corr}}, t)$ -breaks  $\Pi$ 's  $(n_V, q_S, q_V)$ -Correctness; 2.  $(\varepsilon_{\text{Cons}}, t)$ -breaks  $\Pi$ 's  $(n_V, q_V)$ -Consistency; 3.  $(\varepsilon_{\text{Unforg}}, t)$ -breaks  $\Pi$ 's  $(n_S, n_V, q_S, q_V)$ -Unforgeability; or 4.  $(\varepsilon_{\text{OTR}}, t)$ -breaks  $\Pi$ 's  $(n_V, d_S, q_S, q_V)$ -Off-The-Record.

## 4.2 DVS Construction

We present our MDVS construction incrementally.<sup>7</sup> We begin by giving a construction of a (single verifier) DVS scheme (see Algorithm 1) that is Correct (Definition 1), Unforgeable (Definition 3) and Off-The-Record (Definition 4); next, we generalize it into an MDVS scheme (which has to additionally satisfy consistency); finally, we use a technique first introduced by Bader et al. in [1] to make the scheme tightly secure under adaptive corruptions. The building blocks for all our constructions are a NIZK scheme  $\Pi_{\text{NIZK}} = (G, P, V, S := (S_G, S_P))$ , a PKE scheme  $\Pi_{\text{PKE}} = (G, E, D)$ , and a One Way Function  $\Pi_{\text{OWF}} = (S, F)$ .

For modularity, rather than introducing a single language/relation for the NIZK scheme used by our constructions, we will introduce different relations and then define the relation/language for our constructions as the intersection of

<sup>7</sup> We only prove the security of the final MDVS construction given in Section 4.4.

these relations. For example, in Algorithm 1 we consider the language induced by a relation  $R_{\text{DVS}} := R_{\text{DVS-Match}} \cap R_{\text{DVS-Unforg}}$ , where

$$\begin{aligned} \bullet R_{\text{DVS-Match}} &:= \left\{ \left( (\text{pk}_{\text{pp}}, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}), (a, b, r, r_{\text{pp}}) \right) \mid \right. \\ &\quad \left. \left( c_{\text{pp}} = \Pi_{\text{PKE}}.E_{\text{pk}_{\text{pp}}}((m, b, a); r_{\text{pp}}) \right) \wedge \left( c = \Pi_{\text{PKE}}.E_{\text{vpk.pk}}(b; r) \right) \right\}; \\ \bullet R_{\text{DVS-Unforg}} &:= \left\{ \left( (\text{pk}_{\text{pp}}, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}), (a, b, r, r_{\text{pp}}) \right) \mid \right. \\ &\quad \left. (b = 1) \rightarrow (\Pi_{\text{OWF}}.F(a) \in \{\text{spk}.y, \text{vpk}.y\}) \right\}. \end{aligned}$$

The corresponding language is then defined as  $L_{\text{DVS}} := \{(\text{pk}_{\text{pp}}, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}) \mid \exists (a, b, r, r_{\text{pp}}) : ((\text{pk}_{\text{pp}}, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}), (a, b, r, r_{\text{pp}})) \in R_{\text{DVS}}\}$ .

---

**Algorithm 1** DVS scheme construction  $\Pi_{\text{DVS}} = (S, G_S, G_V, \text{Sig}, \text{Vfy}, \text{Forge})$ .

---

```

 $S(1^k)$ 
   $(\text{pk}, \text{sk}) \leftarrow \Pi_{\text{PKE}}.G(1^k)$ 
  return  $\text{pp} := (1^k, \text{crs} \leftarrow \Pi_{\text{NIZK}}.G(1^k), \text{pk})$ 

 $G_S(\text{pp})$ 
   $x \leftarrow \Pi_{\text{OWF}}.S(1^k)$ 
  return  $(\text{spk} := \Pi_{\text{OWF}}.F(x), \text{ssk} := (\text{spk}, x))$ 

 $G_V(\text{pp})$ 
   $(\text{pk}, \text{sk}) \leftarrow \Pi_{\text{PKE}}.G(1^k)$ 
   $x \leftarrow \Pi_{\text{OWF}}.S(1^k)$ 
  return  $(\text{vpk} := (\Pi_{\text{OWF}}.F(x), \text{pk}), \text{vsk} := (\text{vpk}, \text{sk}, x))$ 

 $\text{Sig}_{\text{pp}}(\text{ssk}, \text{vpk}, m)$ 
   $c \leftarrow \Pi_{\text{PKE}}.E_{\text{vpk.pk}}(1; r)$ 
   $c_{\text{pp}} \leftarrow \Pi_{\text{PKE}}.E_{\text{pp.pk}}((m, 1, \text{ssk}.x); r_{\text{pp}})$ 
   $p \leftarrow \Pi_{\text{NIZK}}.P_{\text{crs}}((\text{pp}.pk, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}) \in L_{\text{DVS}}, (\text{ssk}.x, 1, r, r_{\text{pp}}))$ 
  return  $\sigma := (p, c, c_{\text{pp}})$ 

 $\text{Vfy}_{\text{pp}}(\text{spk}, \text{vsk}, m, \sigma := (p, c, c_{\text{pp}}))$ 
   $b \leftarrow \Pi_{\text{NIZK}}.V_{\text{crs}}((\text{pp}.pk, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}) \in L_{\text{DVS}}, p)$ 
  return  $b \wedge \Pi_{\text{PKE}}.D_{\text{vsk.sk}}(c)$ 

 $\text{Forge}_{\text{pp}}(\text{spk}, \text{vpk}, m, \text{vsk})$ 
  if  $\text{vsk} \neq \perp$  then ▷ Forge using verifier's secret key.
     $c \leftarrow \Pi_{\text{PKE}}.E_{\text{vpk.pk}}(1; r)$ 
     $c_{\text{pp}} \leftarrow \Pi_{\text{PKE}}.E_{\text{pp.pk}}((m, 1, \text{vsk}.x); r_{\text{pp}})$ 
     $p \leftarrow \Pi_{\text{NIZK}}.P_{\text{crs}}((\text{pp}.pk, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}) \in L_{\text{DVS}}, (\text{vsk}.x, 1, r, r_{\text{pp}}))$ 
  else ▷ Forge without using verifier's secret key.
     $c \leftarrow \Pi_{\text{PKE}}.E_{\text{vpk.pk}}(0; r)$ 
     $c_{\text{pp}} \leftarrow \Pi_{\text{PKE}}.E_{\text{pp.pk}}((m, 0, 0); r_{\text{pp}})$ 
     $p \leftarrow \Pi_{\text{NIZK}}.P_{\text{crs}}((\text{pp}.pk, \text{spk}, \text{vpk}, m, c, c_{\text{pp}}) \in L_{\text{DVS}}, (0, 0, r, r_{\text{pp}}))$ 
  return  $\sigma := (p, c, c_{\text{pp}})$ 

```

---

In our scheme a signature consists of two ciphertexts,  $c$  and  $c_{\text{pp}}$ , together with a NIZK proof  $p$  which is the key for guaranteeing signature unforgeability. Informally,  $\Pi_{\text{NIZK}}$ 's soundness guarantees that, on one hand, since  $R_{\text{DVS}} \subseteq$

$R_{\text{DVS-Match}}$ , ciphertexts  $c_{\text{pp}}$  and  $c$  encrypt the same bit  $b$ , and on the other hand, since  $R_{\text{DVS}} \subseteq R_{\text{DVS-Unforg}}$ , if this bit  $b$  is 1 (in which case the signature verification succeeds),  $c_{\text{pp}}$  encrypts either the signer's or the verifier's secret key.

### 4.3 A Conceptually Simple MDVS Construction

We now show how to generalize the DVS scheme from before into an MDVS scheme. Our MDVS scheme construction is defined in Algorithm 2 and is analogous to the DVS scheme from before, but adapted to the multi-verifier case. The main difference is that MDVS schemes need to guarantee consistency.

In the following, let  $\vec{\alpha} := ((b_1, a_1), \dots, (b_{|\vec{\alpha}|}, a_{|\vec{\alpha}|}))$ ; we assume for simplicity that all vectors have matching lengths, i.e.  $|\vec{v}| = |\vec{c}| = |\vec{\alpha}|$ .

$$\begin{aligned}
\bullet R_{\text{MDVSstatic-Match}} &:= \left\{ ((\text{pk}_{\text{pp}}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad \left. \left[ c_{\text{pp}} = \Pi_{\text{PKE}}.E_{\text{pk}_{\text{pp}}}((m, b, \vec{\alpha}); r_{\text{pp}}) \right] \wedge \left[ \bigwedge_{i \in \{1, \dots, |\vec{v}|\}} (c_i = \Pi_{\text{PKE}}.E_{v_i.\text{pk}}(b_i; r_i)) \right] \right\} \\
\bullet R_{\text{MDVSstatic-Unforg}} &:= \left\{ ((\text{pk}_{\text{pp}}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad \left. \bigwedge_{i \in \{1, \dots, |\vec{v}|\}} \left( (b_i = 1) \rightarrow (\Pi_{\text{OWF}}.F(a_i) \in \{\text{spk}.y, v_i.y\}) \right) \right\} \\
\bullet R_{\text{MDVSstatic-Cons}} &:= \left\{ ((\text{pk}_{\text{pp}}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad \left. \bigwedge_{i \in \{1, \dots, |\vec{v}|\}} \left( (\Pi_{\text{OWF}}.F(a_i) \neq v_i.y) \rightarrow (b_i = b) \right) \right\}.
\end{aligned}$$

Similarly to  $R_{\text{DVS}}$ , and for the sake of modularity, we define relation  $R_{\text{MDVSstatic}}$  as  $R_{\text{MDVSstatic}} := R_{\text{MDVSstatic-Match}} \cap R_{\text{MDVSstatic-Unforg}} \cap R_{\text{MDVSstatic-Cons}}$ . In Algorithm 2, we consider the respective induced language  $L_{\text{MDVSstatic}} := \{(\text{pk}_{\text{pp}}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \mid \exists(\vec{\alpha}, \vec{r}, r_{\text{pp}}, b) : ((\text{pk}_{\text{pp}}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) \in R_{\text{MDVSstatic}}\}$ .

Note that, since  $R_{\text{MDVSstatic}} \subseteq R_{\text{MDVSstatic-Match}} \cap R_{\text{MDVSstatic-Unforg}}$ ,  $\Pi_{\text{NIZK}}$ 's soundness guarantees that if for any  $i \in \{1, \dots, |\vec{v}|\}$ ,  $c_i$  is an encryption of 1, then  $c_{\text{pp}}$  contains either the signer's secret key or the  $i$ -th verifier's secret key. Similarly, since  $R_{\text{MDVSstatic}} \subseteq R_{\text{MDVSstatic-Match}} \cap R_{\text{MDVSstatic-Cons}}$ ,  $\Pi_{\text{NIZK}}$ 's soundness implies that every designated verifier  $B_j$  whose secret key is not in  $c_{\text{pp}}$ 's underlying plaintext will agree on whether the signature is valid.

### 4.4 Achieving Tight Security under Adaptive Corruptions

We now show how to transform the MDVS scheme from before into one that is tightly secure under adaptive corruptions. The main challenge here is finding a way to embed the challenges from the security games of the underlying PKE and OWF building blocks into the reductions (in such a way that the reduction is

---

tight on the security of the underlying building blocks) while still being able to answer queries for the secret keys of signers and/or verifiers. To achieve this, we rely on a technique that was first introduced in [1]. Essentially, for each party two key-pairs are now sampled; the party's public key are the public keys of each of the underlying key-pairs, and the secret key is the secret key of one (and only one) of these key-pairs. This allows answering secret key queries by the adversary while still being able to embed challenges from the underlying security games into reductions.

Let  $\vec{\alpha} := ((b_1, a_1), \dots, (b_{|\vec{\alpha}|}, a_{|\vec{\alpha}|}))$ ; in the following, vectors are assumed to have matching lengths:

$$\begin{aligned}
\bullet R_{\text{MDVS}^{\text{adap-}}\text{Match}} &:= \left\{ ((\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad (c_{\text{pp}} = \Pi_{\text{PKE}} \cdot E_{\text{pp.pk}}((m, b, \vec{\alpha}); r_{\text{pp}})) \bigwedge \\
&\quad \left. \left[ \bigwedge_{i \in \{1, \dots, |\vec{v}|\}} \left( (c_{i,0} = \Pi_{\text{PKE}} \cdot E_{v_i.\text{pk}_0}(b_i; r_{i,0})) \wedge (c_{i,1} = \Pi_{\text{PKE}} \cdot E_{v_i.\text{pk}_1}(b_i; r_{i,1})) \right) \right] \right\} \\
\bullet R_{\text{MDVS}^{\text{adap-}}\text{Unforg}} &:= \left\{ ((\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad \left. \bigwedge_{i \in \{1, \dots, |\vec{\alpha}|\}} \left( (b_i = 1) \rightarrow (\Pi_{\text{OWF}} \cdot F(a_i) \in \{\text{spk.y}_0, \text{spk.y}_1, v_i.y_0, v_i.y_1\}) \right) \right\} \\
\bullet R_{\text{MDVS}^{\text{adap-}}\text{Cons}} &:= \left\{ ((\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) : \right. \\
&\quad \left. \bigwedge_{i \in \{1, \dots, |\vec{\alpha}|\}} \left( (\Pi_{\text{OWF}} \cdot F(a_i) \notin \{v_i.y_0, v_i.y_1\}) \rightarrow (b_i = b) \right) \right\}.
\end{aligned}$$

As in Section 4.3, we define  $R_{\text{MDVS}^{\text{adap}}} := R_{\text{MDVS}^{\text{adap-}}\text{Match}} \cap R_{\text{MDVS}^{\text{adap-}}\text{Unforg}} \cap R_{\text{MDVS}^{\text{adap-}}\text{Cons}}$ ; in Algorithm 3, we consider the language  $L_{\text{MDVS}^{\text{adap}}}$  that is induced by  $R_{\text{MDVS}^{\text{adap}}}$ , which is defined as:  $L_{\text{MDVS}^{\text{adap}}} := \{(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \mid \exists (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b) : ((\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}), (\vec{\alpha}, \vec{r}, r_{\text{pp}}, b)) \in R_{\text{MDVS}^{\text{adap}}}\}$ .

**4.4.1 Security Analysis of  $\Pi_{\text{MDVS}}^{\text{adap}}$**  The theorem below gives an informal summary of our construction's security properties. The formal security theorems (and the corresponding full proofs) are in the appendix (see Section B.2).

**Theorem 1 (Informal).** *If  $\Pi_{\text{PKE}}$  is correct and tightly multi-user and multi-challenge IND-CPA and IK-CPA secure under non-adaptive corruptions,  $\Pi_{\text{NIZK}}$  is complete, sound, tightly multi-statement adaptive zero-knowledge and tightly multi-statement simulation sound, and  $\Pi_{\text{OWF}}$  is tightly multi-instance secure under non-adaptive corruptions, then  $\Pi_{\text{MDVS}}^{\text{adap}}$  is:*

1. *tightly correct (Theorem 3);*
2. *tightly consistent under adaptive corruptions (Theorem 4);*
3. *tightly unforgeable under adaptive corruptions (Theorem 5); and*
4. *tightly off-the-record under adaptive corruptions (Theorem 6).*

**4.4.2 On Efficiently Instantiating the NIZK Relations** All the relations we consider consist of checking a number of equations over a pairing-friendly group, when implemented with suitably algebraic primitives. (For instance, we can use ElGamal [7] as the PKE scheme, and a pairing with one fixed input as the One Way Function.) Then, we can use a simulation-sound variant of Groth-Sahai proofs [10, 11] as a compatible NIZK scheme to prove these relations. This yields proofs that are only linear-sized in the number of witness variables and equations. Of course, this will result in an unoptimized solution that may not be quite practical yet.

## 5 PKEBC Scheme with Linear Ciphertext Size and Decryption Time

A PKEBC scheme  $\Pi$  is a quadruple  $\Pi = (S, G, E, D)$  of PPTs, where:

- $S$ : on input  $1^k$ , generates public parameters  $\mathbf{pp}$ ;
- $G$ : on input  $\mathbf{pp}$ , generates a receiver key-pair  $(\mathbf{pk}, \mathbf{sk})$ ;
- $E$ : on input  $(\mathbf{pp}, \vec{v}, m)$ , where  $\vec{v}$  is a vector of public keys of the intended receivers and  $m$  is the message, generates a ciphertext  $c$ ;
- $D$ : on input  $(\mathbf{pp}, \mathbf{sk}, c)$ , where  $\mathbf{sk}$  is the receiver’s secret key,  $D$  decrypts  $c$  using  $\mathbf{sk}$ , and outputs the decrypted receiver-vector/message pair  $(\vec{v}, m)$  (or  $\perp$  if the ciphertext did not decrypt correctly).

In this section we introduce new security notions capturing the security of PKEBC schemes under adaptive corruptions and give a new construction of a PKEBC scheme that not only is tightly secure under these stronger notions, but also for which both the ciphertext size and the decryption time only grow linearly with the number of receivers.

### 5.1 Security Notions for Adaptive Corruptions

The security notions we now introduce are a strengthening of the original ones introduced by Maurer et al. in [17], but capturing the security of PKEBC schemes under adaptive corruptions. More concretely, in the Correctness, Robustness and Consistency notions adversaries are now allowed to query for the secret keys of any receiver and still win the game; in the  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security games—a combination of the original IND-CCA-2 and IK-CCA-2 security notions [17] capturing adaptive corruptions—adversaries can now corrupt parties adaptively. (Our  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security notion can also be interpreted as a variant of the notion introduced by Lee et al. in [14]—which captures the IND-CCA-2 security of PKE schemes under adaptive corruptions—but adapted for PKEBC schemes and also capturing anonymity.)

We now introduce some oracles that the game systems ahead provide to the adversaries. In the following, consider a PKEBC scheme  $\Pi = (S, G, E, D)$  with message space  $\mathcal{M}$ . The oracles below are defined for a game-system with (an implicitly defined) security parameter  $k$ :

**Public Parameters Oracle:**  $\mathcal{O}_{PP}$

1. On the first call, compute and store  $\text{pp} \leftarrow S(1^k)$ ; output  $\text{pp}$ ;
2. On subsequent calls, output the previously generated  $\text{pp}$ .

**Secret Key Generation Oracle:**  $\mathcal{O}_{SK}(B_j)$

1. If  $\mathcal{O}_{SK}$  was queried on  $B_j$  before, simply look up and return the previously generated key for  $B_j$ ;
2. Otherwise, store  $(\text{pk}_j, \text{sk}_j) \leftarrow G(\text{pp})$  as  $B_j$ 's key-pair, and output  $(\text{pk}_j, \text{sk}_j)$ .

**Public Key Generation Oracle:**  $\mathcal{O}_{PK}(B_j)$

1.  $(\text{pk}_j, \text{sk}_j) \leftarrow \mathcal{O}_{SK}(B_j)$ ;
2. Output  $\text{pk}_j$ .

**Encryption Oracle:**  $\mathcal{O}_E(\vec{V}, m)$

1.  $\vec{v} \leftarrow (\mathcal{O}_{PK}(V_1), \dots, \mathcal{O}_{PK}(V_{|\vec{V}|}))$ ;
2. Create and output a fresh encryption  $c \leftarrow E_{\text{pp}, \vec{v}}(m)$ .

**Decryption Oracle:**  $\mathcal{O}_D(B_j, c)$

1. Query  $\mathcal{O}_{SK}(B_j)$  to obtain the corresponding secret-key  $\text{sk}_j$ ;
2. Decrypt  $c$  using  $\text{sk}_j$ ,  $(\vec{v}, m) \leftarrow D_{\text{pp}, \text{sk}_j}(c)$ , and then output the resulting receivers-message pair  $(\vec{v}, m)$ , or  $\perp$  (if  $(\vec{v}, m) = \perp$ , i.e. the ciphertext is not valid with respect to  $B_j$ 's secret key).

**Definition 5 (Correctness).** *Game  $\mathbf{G}^{\text{Corr}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if there are two queries  $q_E$  and  $q_D$  to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, where  $q_E$  has input  $(\vec{V}, m)$  and  $q_D$  has input  $(B_j, c)$ , satisfying  $B_j \in \vec{V}$ , the input  $c$  in  $q_D$  is the output of  $q_E$ , and the output of  $q_D$  is either  $\perp$  or  $(\vec{v}', m')$  with  $(\vec{v}, m) \neq (\vec{v}', m')$ . The advantage of  $\mathbf{A}$  in winning the Correctness game, denoted  $\text{Adv}^{\text{Corr}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Corr}}$  as described above.*

An adversary  $\mathbf{A}$   $(\varepsilon_{\text{Corr}}, t)$ -breaks the  $(n, d_E, q_E, q_D)$ -Correctness of a PKEBC scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n$  different parties, makes at most  $q_E$  and  $q_D$  queries to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, with the sum of lengths of the party vectors input to  $\mathcal{O}_E$  being at most  $d_E$ , and satisfies  $\text{Adv}^{\text{Corr}}(\mathbf{A}) \geq \varepsilon_{\text{Corr}}$ .

**Definition 6 (Robustness).** *Game  $\mathbf{G}^{\text{Rob}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if there are two queries  $q_E$  and  $q_D$  to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, where  $q_E$  has input  $(\vec{V}, m)$  and  $q_D$  has input  $(B_j, c)$ , satisfying  $B_j \notin \vec{V}$ , the input  $c$  in  $q_D$  is the output of  $q_E$ , and the output of  $q_D$  is  $(\vec{v}', m')$  with  $(\vec{v}', m') \neq \perp$ . The advantage of  $\mathbf{A}$  in winning the Robustness game is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Rob}}$  as described above, and is denoted  $\text{Adv}^{\text{Rob}}(\mathbf{A})$ .*

An adversary  $\mathbf{A}$   $(\varepsilon_{\text{Rob}}, t)$ -breaks the Robustness of a PKEBC scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$  and satisfies  $\text{Adv}^{\text{Rob}}(\mathbf{A}) \geq \varepsilon_{\text{Rob}}$ .

**Definition 7 (Consistency).** Game  $\mathbf{G}^{\text{Cons}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if there is a ciphertext  $c$  such that  $\mathcal{O}_D$  is queried on inputs  $(B_i, c)$  and  $(B_j, c)$  for some  $B_i$  and  $B_j$  (possibly with  $B_i = B_j$ ), query  $\mathcal{O}_D(B_i, c)$  outputs some  $(\vec{v}, m)$  satisfying  $(\vec{v}, m) \neq \perp$  with  $\text{pk}_j \in \vec{v}$  (where  $\text{pk}_j$  is  $B_j$ 's public key), and query  $\mathcal{O}_D(B_j, c)$  does not output  $(\vec{v}, m)$ . The advantage of  $\mathbf{A}$  in winning the Consistency game is denoted  $\text{Adv}^{\text{Cons}}(\mathbf{A})$  and corresponds to the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Cons}}$ .

We say that an adversary  $\mathbf{A}$   $(\varepsilon_{\text{Cons}}, t)$ -breaks the  $(n, q_D)$ -Consistency of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$  and  $\mathcal{O}_D$  on at most  $n$  different parties, makes at most  $q_D$  queries to  $\mathcal{O}_D$  and satisfies  $\text{Adv}^{\text{Cons}}(\mathbf{A}) \geq \varepsilon_{\text{Cons}}$ .

Below we present the definition of  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security. This notion is a combination of the original IND-CCA-2 and IK-CCA-2 security notions introduced in [17] that captures adaptive security (i.e. the adversary is allowed to corrupt parties adaptively). The games defined by this definition provide adversaries with access to the oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$  and  $\mathcal{O}_{PK}$  defined above, as well as to oracles  $\mathcal{O}_E$  and  $\mathcal{O}_D$  defined below:

**Encryption Oracle:**  $\mathcal{O}_E((\vec{V}_0, m_0), (\vec{V}_1, m_1))$

1. For game system  $\mathbf{G}_{\mathbf{b}}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}$ , encrypt  $m_{\mathbf{b}}$  under  $\vec{v}_{\mathbf{b}}$ , the vector of public keys corresponding to  $\vec{V}_{\mathbf{b}}$ ; output  $c$ .

**Decryption Oracle:**  $\mathcal{O}_D(B_j, c)$

1. If  $c$  was the output of some query to  $\mathcal{O}_E$ , output **test**;
2. Otherwise, compute and output  $(\vec{v}, m) \leftarrow D_{\text{pp}, \text{sk}_j}(c)$ , where  $\text{sk}_j$  is  $B_j$ 's secret key.

**Definition 8 ((IND + IK)-CCA-2<sup>adap</sup> Security).** For  $\mathbf{b} \in \{0, 1\}$ , game system  $\mathbf{G}_{\mathbf{b}}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if it outputs a guess bit  $b'$  satisfying  $b' = \mathbf{b}$  and for every query  $\mathcal{O}_E((\vec{V}_0, m_0), (\vec{V}_1, m_1))$ : 1.  $|\vec{V}_0| = |\vec{V}_1|$ ; 2.  $|m_0| = |m_1|$ ; and 3. there is no query to  $\mathcal{O}_{SK}$  on any  $B_j \in \text{Set}(\vec{V}_0) \cup \text{Set}(\vec{V}_1)$  at any point during the game. We define the advantage of  $\mathbf{A}$  in winning the  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  game as

$$\text{Adv}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}} = \text{win}] + \Pr[\mathbf{AG}_1^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}} = \text{win}] - 1 \right|.$$

We say that an adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n, d_E, q_E, q_D)$ - $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries the oracles it has access to on at most  $n$  different parties, makes at most  $q_E$  and  $q_D$  queries to oracles  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, with the sum of lengths of all the party vectors input to  $\mathcal{O}_E$  being at most  $d_E$ , and satisfies  $\text{Adv}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) \geq \varepsilon$ . Finally, we say that  $\Pi$  is

$$(\varepsilon_{\text{Corr}}, \varepsilon_{\text{Rob}}, \varepsilon_{\text{Cons}}, \varepsilon_{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}, t, n, d_E, q_E, q_D, \text{adap})\text{-secure},$$

- if there is no adversary  $\mathbf{A}$  that: 1.  $(\varepsilon_{\text{Corr}}, t)$ -breaks  $\Pi$ 's  $(n, d_E, q_E, q_D)$ -Correctness; 2.  $(\varepsilon_{\text{Rob}}, t)$ -breaks  $\Pi$ 's Robustness; 3.  $(\varepsilon_{\text{Cons}}, t)$ -breaks  $\Pi$ 's  $(n, q_D)$ -Consistency; or 4.  $(\varepsilon_{(\text{IND}+\text{IK})\text{-CCA-2}^{\text{adap}}, t})$ -breaks  $\Pi$ 's  $(n, d_E, q_E, q_D)$ - $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security.

## 5.2 Achieving Linear Ciphertext Size

As before, we present our PKEBC construction incrementally (and only prove the security of the final PKEBC construction given Section 5.4). Our first PKEBC scheme is defined in Algorithm 4. Like Maurer et al.'s scheme [17], our construction is a generalization of Naor-Yung's PKE scheme for multiple receivers (see [19]). However, while Maurer et al.'s scheme encrypts, for each receiver, the vector of all receivers' public keys plus the message—leading not only to quadratic sized ciphertexts but also to quadratic encryption and decryption time—our scheme instead relies on a SKE scheme  $\Pi_{\text{SKE}}$  to encrypt the vector of all receivers plus the message under a key  $k$  that is then encrypted under each receiver's public key, resembling the hybrid encryption technique [22]. Furthermore, while Maurer et al.'s construction relies on a binding commitment scheme in order to achieve consistency, our scheme instead uses a PKE scheme: note that as long as a PKE key-pair  $(\text{pk}, \text{sk})$  is sampled honestly, by the correctness of the PKE scheme, the encryption of any message  $m$  under  $\text{pk}$  also works as a commitment to  $m$ .<sup>8</sup> The building blocks of this first scheme consist of a PKE scheme  $\Pi_{\text{PKE}} = (G, E, D)$ , a SKE scheme  $\Pi_{\text{SKE}} = (G, E, D)$  and a NIZK scheme  $\Pi_{\text{NIZK}} = (G, P, V, S := (S_G, S_P))$ . In the following, vectors are assumed to have matching lengths; consider relation  $R_{\text{PKEBC}^{\text{lin-ctxt}}}$  defined as

$$R_{\text{PKEBC}^{\text{lin-ctxt}}} := \left\{ \left( (1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}') \right) : \right. \quad (5.1)$$

$$\left. \begin{aligned} & (k_{\text{sym}} = \Pi_{\text{SKE}} \cdot G(1^k; r_{\text{sym}})) \wedge (c_{\text{sym}} = \Pi_{\text{SKE}} \cdot E(k_{\text{sym}}, (r_{\text{pp}}, \vec{v}, m); r_{\text{sym}}')) \wedge \\ & \left[ \bigwedge_{j \in \{1, \dots, |\vec{c}|\}} (c_j = \Pi_{\text{PKE}} \cdot E_{v_j}(k_{\text{sym}}; r_j)) \right] \wedge (c_{\text{pp}} = \Pi_{\text{PKE}} \cdot E_{\text{pk}_{\text{pp}}}((\vec{v}, m); r_{\text{pp}})) \end{aligned} \right\}.$$

In Algorithm 4, we consider the language  $L_{\text{PKEBC}^{\text{lin-ctxt}}}$  that is induced by relation  $R_{\text{PKEBC}^{\text{lin-ctxt}}}$ :  $L_{\text{PKEBC}^{\text{lin-ctxt}}} := \{ (1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \mid \exists (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}') : ((1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}')) \in R_{\text{PKEBC}^{\text{lin-ctxt}}} \}$ .

## 5.3 Achieving Linear Time Decryption

As discussed in Section 2.2, while the scheme given in Section 5.2 already achieves linear size ciphertexts and linear time encryption, it does not achieve linear time decryption. We now show how to modify  $\Pi_{\text{PKEBC}^{\text{lin-ctxt}}}$  to achieve linear time decryption. The new scheme, denoted  $\Pi_{\text{PKEBC}^{\text{lin-dec}}}$ , is defined in Algorithm 5, and

<sup>8</sup> At a more technical level, replacing the binding commitment scheme of Maurer et al.'s PKEBC construction by a PKE scheme also serves the purpose of allowing the  $(\text{IND} + \text{IK})\text{-CCA-2}$  security reductions to handle decryption queries.

---

**Algorithm 4** Construction of PKEBC scheme  $\Pi_{\text{PKEBC}}^{\text{lin-ctxt}} = (S, G, E, D)$ .

---

```

 $S(1^k)$ 
   $(\text{pk}, \text{sk}) \leftarrow \Pi_{\text{PKE}} \cdot G(1^k)$ 
  return  $\text{pp} := (1^k, \text{crs} \leftarrow \Pi_{\text{NIZK}} \cdot G(1^k), \text{pk})$ 

 $G(\text{pp})$ 
   $(\text{pk}', \text{sk}') \leftarrow \Pi_{\text{PKE}} \cdot G(1^k)$ 
  return  $(\text{pk} := \text{pk}', \text{sk} := (\text{pk}, \text{sk}'))$ 

 $E_{\text{pp}}(\vec{v} := (\text{pk}_1, \dots, \text{pk}_{|\vec{v}|}), m)$ 
   $c_{\text{pp}} \leftarrow \Pi_{\text{PKE}} \cdot E_{\text{pp}, \text{pk}}((\vec{v}, m); r_{\text{pp}})$ 
   $k_{\text{sym}} \leftarrow \Pi_{\text{SKE}} \cdot G(1^k; r_{\text{sym}})$ 
   $c_{\text{sym}} \leftarrow \Pi_{\text{SKE}} \cdot E_{k_{\text{sym}}}((r_{\text{pp}}, \vec{v}, m); r_{\text{sym}}')$ 
  for each  $j \in \{1, \dots, |\vec{v}|\}$  do
     $c_j \leftarrow \Pi_{\text{PKE}} \cdot E_{v_j}(k_{\text{sym}}; r_j)$ 
   $(\vec{r}, \vec{c}) := ((r_1, \dots, r_{|\vec{v}|}), (c_1, \dots, c_{|\vec{v}|}))$ 
   $p \leftarrow \Pi_{\text{NIZK}} \cdot P_{\text{crs}}((1^k, \text{pp}, \text{pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{lin-ctxt}}}, (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}'))$ 
  return  $(p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$ 

 $D_{\text{pp}}(\text{sk}, c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}}))$ 
  if  $\Pi_{\text{NIZK}} \cdot V_{\text{crs}}((1^k, \text{pp}, \text{pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{lin-ctxt}}}, p) = \text{valid}$  then
    for  $j = 1, \dots, |\vec{c}|$  do
       $k_{\text{sym}} \leftarrow \Pi_{\text{PKE}} \cdot D_{\text{sk}, \text{sk}'}(c_j)$ 
       $(r_{\text{pp}}, \vec{v}, m) \leftarrow \Pi_{\text{SKE}} \cdot D_{k_{\text{sym}}}(c_{\text{sym}})$ 
      if  $(r_{\text{pp}}, \vec{v}, m) \neq \perp \wedge \text{sk}, \text{pk} = v_j$  then
        if  $c_{\text{pp}} = \Pi_{\text{PKE}} \cdot E_{\text{pp}, \text{pk}}((\vec{v}, m); r_{\text{pp}})$  then
          return  $(\vec{v}, m)$ 
    return  $\perp$ 

```

---

uses the same building blocks as  $\Pi_{\text{PKEBC}}^{\text{lin-ctxt}}$ . In the following, vectors are assumed to have matching lengths; furthermore, to simplify the definition of the relations below, we introduce the following predicate:

$$\text{CtxtMatch}(\text{pk}, \text{pk}', r_0, r_1, r_2, \alpha, k, c_0, c_1, c_2) := ((c_0, c_1, c_2) = (\Pi_{\text{PKE}} \cdot E_{\text{pk}}(\alpha; r_0), \Pi_{\text{PKE}} \cdot E_{\text{pk}'}(r_0; r_1), \Pi_{\text{PKE}} \cdot E_{\text{pk}'}(k; r_2))). \quad (5.2)$$

Consider relation  $R_{\text{PKEBC}^{\text{lin-dec}}}$  defined as

$$R_{\text{PKEBC}^{\text{lin-dec}}} := \left\{ ((1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}')) : \right. \quad (5.3)$$

$$\left. \begin{aligned} & (k_{\text{sym}} = \Pi_{\text{SKE}} \cdot G(1^k; r_{\text{sym}})) \wedge (c_{\text{sym}} = \Pi_{\text{SKE}} \cdot E(k_{\text{sym}}, (\vec{v}, m); r_{\text{sym}}')) \wedge \\ & \left[ \bigwedge_{j \in \{1, \dots, |\vec{c}|\}} \text{CtxtMatch}(\text{pk}_{\text{pp}}, v_j, r_{j,0}, r_{j,1}, r_{j,2}, v_j, k_{\text{sym}}, c_{j,0}, c_{j,1}, c_{j,2}) \right] \wedge \\ & (c_{\text{pp}} = \Pi_{\text{PKE}} \cdot E_{\text{pk}_{\text{pp}}}(m; r_{\text{pp}})) \end{aligned} \right\}.$$

In Algorithm 5, we consider the language  $L_{\text{PKEBC}^{\text{lin-dec}}}$  that is induced by relation  $R_{\text{PKEBC}^{\text{lin-dec}}}$ :  $L_{\text{PKEBC}^{\text{lin-dec}}} := \{(1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \mid \exists (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}') : ((1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}')) \in R_{\text{PKEBC}^{\text{lin-dec}}}\}$ .

**return**  $\Pi_{\text{SKE}}.D_{k_{\text{sym}}}(c_{\text{sym}})$

**return**  $\perp$

---

#### 5.4 Achieving Tight Security under Adaptive Corruptions

Finally, we modify  $\Pi_{\text{PKEBC}}^{\text{lin-dec}}$  to get a PKEBC scheme that is tightly security under adaptive corruptions. Informally, we use the same two-key technique that we used for our MDVS scheme construction [1, 19]. In other words, in our scheme each party generates two key-pairs,  $(\text{pk}_0, \text{sk}_0)$  and  $(\text{pk}_1, \text{sk}_1)$ , and then discards one of the secret keys  $\text{sk}_b$  picked uniformly at random. The new scheme is denoted  $\Pi_{\text{PKEBC}}^{\text{adap}}$  and is defined in Algorithm 6. Similarly to  $\Pi_{\text{PKEBC}}^{\text{lin-dec}}$ ,  $\Pi_{\text{PKEBC}}^{\text{adap}}$  uses the same building blocks as  $\Pi_{\text{PKEBC}}^{\text{lin-ctxt}}$ . Consider relation  $R_{\text{PKEBC}^{\text{adap}}}$  defined as

$$\begin{aligned}
 R_{\text{PKEBC}^{\text{adap}}} := & \left\{ ((1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}')) \mid \right. & (5.4) \\
 & (k_{\text{sym}} = \Pi_{\text{SKE}}.G(1^k; r_{\text{sym}})) \wedge (c_{\text{sym}} = \Pi_{\text{SKE}}.E(k_{\text{sym}}, (\vec{v}, m); r_{\text{sym}}')) \\
 & \wedge (c_{\text{pp}} = \Pi_{\text{PKE}}.E_{\text{pk}_{\text{pp}}}(m; r_{\text{pp}})) \wedge \left[ \bigwedge_{j \in \{1, \dots, |\vec{c}|\}, b \in \{0,1\}} \right. \\
 & \left. \left. \text{CtxtMatch}(\text{pk}_{\text{pp}}, v_j, \text{pk}_b, r_{j,0}, r_{j,b,1}, r_{j,b,2}, v_j, k_{\text{sym}}, c_{j,0}, c_{j,b,1}, c_{j,b,2}) \right] \right\},
 \end{aligned}$$

where  $\text{CtxtMatch}$  is as in Equation 5.2. In Algorithm 6, we consider the following language:  $L_{\text{PKEBC}^{\text{adap}}} := \{(1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \mid \exists (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}') : ((1^k, \text{pk}_{\text{pp}}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}), (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}')) \in R_{\text{PKEBC}^{\text{adap}}}\}$ .

---

**Algorithm 6** Construction  $\Pi_{\text{PKEBC}}^{\text{adap}}$ .

---

```

 $S(1^k)$ 
   $(\text{pk}, \text{sk}) \leftarrow \Pi_{\text{PKE}}.G(1^k)$ 
  return  $\text{pp} := (1^k, \text{crs} \leftarrow \Pi_{\text{NIZK}}.G(1^k), \text{pk})$ 

 $G(\text{pp})$ 
   $(\text{pk}_0, \text{sk}_0) \leftarrow \Pi_{\text{PKE}}.G(1^k)$

  for each  $j \in \{1, \dots, |\vec{v}|\}$  do
     $c_{j,0} \leftarrow \Pi_{\text{PKE}}.E_{\text{pp.pk}}(v_j; r_{j,0})$ 
    for each  $b \in \{0, 1\}$  do
       $(c_{j,b,1}, c_{j,b,2}) \leftarrow (\Pi_{\text{PKE}}.E_{v_j.\text{pk}_b}(r_{j,0}; r_{j,b,1}), \Pi_{\text{PKE}}.E_{v_j.\text{pk}_b}(k_{\text{sym}}; r_{j,b,2}))$ 
       $(r_j, c_j) \leftarrow ((r_{j,0}, r_{j,0,1}, r_{j,0,2}, r_{j,1,1}, r_{j,1,2}), (c_{j,0}, c_{j,0,1}, c_{j,0,2}, c_{j,1,1}, c_{j,1,2}))$ 
   $(\vec{r}, \vec{c}) := ((r_1, \dots, r_{|\vec{v}|}), (c_1, \dots, c_{|\vec{v}|}))$ 
   $p \leftarrow \Pi_{\text{NIZK}}.P_{\text{crs}}((1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}, (\vec{v}, m, r_{\text{pp}}, \vec{r}, r_{\text{sym}}, r_{\text{sym}}'))$ 
  return  $(p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$ 

 $D_{\text{pp}}(\text{sk}, c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}}))$ 
  if  $\Pi_{\text{NIZK}}.V_{\text{crs}}((1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}, p) = \text{valid}$  then
    for  $j = 1, \dots, |\vec{c}|$  do
       $r \leftarrow \Pi_{\text{PKE}}.D_{\text{sk.sk}}(c_{j,\text{sk},b,1})$ 
      if  $r \neq \perp \wedge \Pi_{\text{PKE}}.E_{\text{pp.pk}}(\text{sk.pk}; r) = c_{j,0}$  then
         $k_{\text{sym}} \leftarrow \Pi_{\text{PKE}}.D_{\text{sk.sk}}(c_{j,\text{sk},b,2})$ 
        return  $\Pi_{\text{SKE}}.D_{k_{\text{sym}}}(c_{\text{sym}})$ 
  return  $\perp$ 

```

---

**5.4.1 Security Analysis of  $\Pi_{\text{PKEBC}}^{\text{adap}}$**  The following theorem gives an informal overview of the security properties of our PKEBC scheme construction. The formal theorems and corresponding full proofs are in the appendix (see Section B.3).

**Theorem 2 (Informal).** *If  $\Pi_{\text{PKE}}$  is correct and tightly multi-user and multi-challenge IND-CPA and IK-CPA secure under non-adaptive corruptions,  $\Pi_{\text{NIZK}}$  is complete, sound, tightly multi-statement adaptive zero-knowledge and tightly multi-statement simulation sound, and  $\Pi_{\text{SKE}}$  is correct and tightly multi-instance IND-CPA secure, then  $\Pi_{\text{PKEBC}}^{\text{adap}}$  is:*

1. tightly correct (Theorem 7);
2. tightly robust (Theorem 8);
3. tightly consistent (Theorem 9); and
4. tightly (IND + IK)-CCA-2<sup>adap</sup> secure under adaptive corruptions (Theorem 10).

## 6 Multi-Designated Receiver Signed Public Key Encryption Schemes

An MDRS-PKE scheme  $\Pi$  is a 6-tuple of PPTs  $\Pi = (S, G_S, G_R, E, D, Forge)$ , where:

- $S$ : on input  $1^k$ , generates public parameters  $\mathbf{pp}$ ;
- $G_S$ : on input  $\mathbf{pp}$ , generates a sender key-pair  $(\mathbf{spk}, \mathbf{ssk})$ ;
- $G_R$ : on input  $\mathbf{pp}$ , generates a receiver key-pair  $(\mathbf{rpk}, \mathbf{rsk})$ ;
- $E$ : on input  $(\mathbf{pp}, \mathbf{ssk}, \vec{v}, m)$ , where  $\mathbf{ssk}$  is the secret sending key,  $\vec{v}$  is a vector of public keys of the intended receivers, and  $m$  is the message, generates a ciphertext  $c$ ;
- $D$ : on input  $(\mathbf{pp}, \mathbf{rsk}, c)$ , where  $\mathbf{rsk}$  is the receiver’s secret key,  $D$  decrypts  $c$  using  $\mathbf{rsk}$ , obtaining a triple sender/receiver-vector/message  $(\mathbf{spk}, \vec{v}, m)$  (or  $\perp$  if decryption fails) which it then outputs;
- $Forge$ : on input  $(\mathbf{pp}, \mathbf{spk}, \vec{v}, m, \vec{s})$ , where  $\mathbf{spk}$  is the sender’s public key,  $\vec{v}$  is a vector of public keys of the intended receivers,  $m$  is the message and  $\vec{s}$  is a vector of designated receivers’ secret keys—with  $|\vec{s}| = |\vec{v}|$  and where for  $i \in \{1, \dots, |\vec{v}|\}$ , either  $s_i = \perp$  or  $s_i$  is the secret key corresponding to the  $i$ -th public key of  $\vec{v}$ , i.e.  $v_i$ —generates a ciphertext  $c$ .

Analogously to Section 4, in this section we introduce new (stronger) security notions for MDRS-PKE schemes (see Definitions 12 and 13). Then, we briefly describe how one use the MDVS and PKEBC constructions from before to obtain an MDRS-PKE scheme with the desired properties (by following the construction given by Maurer et al. in [17]), and argue why the scheme is secure with respect to our new stronger MDRS-PKE security notions.

### 6.1 Security Notions

Below we state the notions of Correctness, Consistency, Unforgeability, (IND + IK)-CCA-2<sup>adap</sup> and Off-The-Record for MDRS-PKE schemes. Analogously to the new MDVS Off-The-Record security notion we introduced in Section 4.1 (Definition 4), the (IND + IK)-CCA-2<sup>adap</sup> and Off-The-Record security notions we now present (Definitions 12 and 13, respectively), allow the adversary to obtain the sender’s secret key; and analogously to the new PKEBC security notions we introduced in Section 5.1 (in particular Definition 8), our new MDRS-PKE security notions capture the setting where the adversary can adaptively corrupt parties (see Definition 12). The security notions we now present are thus an enhancement over the original ones given in [17].

Let  $\Pi = (S, G_S, G_V, E, D, Forge)$  be an MDRS-PKE scheme with message space  $\mathcal{M}$ . The oracles below are defined for a game-system with (an implicitly defined) security parameter  $k$ :

#### Public Parameter Generation Oracle: $\mathcal{O}_{PP}$

1. On the first call, compute  $\mathbf{pp} \leftarrow S(1^k)$ ; output  $\mathbf{pp}$ ;
2. On subsequent calls, simply output  $\mathbf{pp}$ .

**Sender Key-Pair Oracle:**  $\mathcal{O}_{SK}(A_i)$

1. On the first call on input  $A_i$ , compute and store  $(\mathbf{spk}_i, \mathbf{ssk}_i) \leftarrow G_S(\text{pp})$ ; output  $(\mathbf{spk}_i, \mathbf{ssk}_i)$ ;
2. On subsequent calls, simply output  $(\mathbf{spk}_i, \mathbf{ssk}_i)$ .

**Receiver Key-Pair Oracle:**  $\mathcal{O}_{RK}(B_j)$

1. Analogous to the Sender Key-Pair Oracle.

**Sender Public-Key Oracle:**  $\mathcal{O}_{SPK}(A_i)$

1.  $(\mathbf{spk}_i, \mathbf{ssk}_i) \leftarrow \mathcal{O}_{SK}(A_i)$ ; output  $\mathbf{spk}_i$ .

**Receiver Public-Key Oracle:**  $\mathcal{O}_{RPK}(B_j)$

1. Analogous to the Sender Public-Key Oracle.

**Encryption Oracle:**  $\mathcal{O}_E(A_i, \vec{V}, m)$

1.  $(\mathbf{spk}_i, \mathbf{ssk}_i) \leftarrow \mathcal{O}_{SK}(A_i)$ ;
2.  $\vec{v} \leftarrow (\mathcal{O}_{RPK}(V_1), \dots, \mathcal{O}_{RPK}(V_{|\vec{V}|}))$ ;
3. Output  $c \leftarrow E_{\text{pp}}(\mathbf{ssk}_i, \vec{v}, m)$ .

**Decryption Oracle:**  $\mathcal{O}_D(B_j, c)$

1.  $(\mathbf{rpk}_j, \mathbf{rsk}_j) \leftarrow \mathcal{O}_{RK}(B_j)$ ;
2. Output  $(\mathbf{spk}, \vec{v} := (\mathbf{rpk}_1, \dots, \mathbf{rpk}_{|\vec{v}|}), m) \leftarrow D_{\text{pp}}(\mathbf{rsk}_j, c)$ .

**Definition 9 (Correctness).** Game system  $\mathbf{G}^{\text{Corr}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if there are two queries  $q_E$  and  $q_D$  to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, where  $q_E$  has input  $(A_i, \vec{V}, m)$  and  $q_D$  has input  $(B_j, c)$ , satisfying  $B_j \in \vec{V}$ , the input  $c$  in  $q_D$  is the output of  $q_E$ , the output of  $q_D$  is  $(\mathbf{spk}'_i, \vec{v}', m')$  with  $(\mathbf{spk}'_i, \vec{v}', m') = \perp$  or  $(\mathbf{spk}'_i, \vec{v}', m') \neq (\mathbf{spk}_i, \vec{v}, m)$ —where  $\mathbf{spk}_i$  is  $A_i$ 's public key and  $\vec{v}$  is the corresponding vector of public keys of the parties of  $\vec{V}$ . The advantage of  $\mathbf{A}$  in winning the Correctness game, denoted  $\text{Adv}^{\text{Corr}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Corr}}$  as described above.

**Definition 10 (Consistency).** Game system  $\mathbf{G}^{\text{Cons}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if there is a ciphertext  $c$  such that  $\mathcal{O}_D$  is queried on inputs  $(B_i, c)$  and  $(B_j, c)$  for some  $B_i$  and  $B_j$  (possibly with  $B_i = B_j$ ), there is no prior query on either  $B_i$  or  $B_j$  to  $\mathcal{O}_{RK}$ , query  $\mathcal{O}_D(B_i, c)$  outputs some  $(\mathbf{spk}_l, \vec{v}, m)$  satisfying  $(\mathbf{spk}_l, \vec{v}, m) \neq \perp$ ,  $\mathbf{spk}_l$  is some party  $A_l$ 's public sender key (i.e.  $\mathcal{O}_{SPK}(A_l) = \mathbf{spk}_l$ ) and  $\mathbf{rpk}_j \in \vec{v}$  (where  $\mathbf{rpk}_j$  is  $B_j$ 's public key), and query  $\mathcal{O}_D(B_j, c)$  does not output the same triple  $(\mathbf{spk}_l, \vec{v}, m)$ . The advantage of  $\mathbf{A}$  in winning the Consistency game is denoted  $\text{Adv}^{\text{Cons}}(\mathbf{A})$  and corresponds to the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Cons}}$  as described above.

**Definition 11 (Unforgeability).** Game system  $\mathbf{G}^{\text{Unforg}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ . We say that  $\mathbf{A}$  wins the game if there is a query  $q$  to  $\mathcal{O}_D$  on an input  $(B_j, c)$  that outputs  $(\mathbf{spk}_i, \vec{v}, m) \neq \perp$  with  $\mathbf{spk}_i$  being some party  $A_i$ 's sender public key (i.e.  $\mathcal{O}_{SPK}(A_i) = \mathbf{spk}_i$ ), there was no query  $\mathcal{O}_E(A_i, \vec{V}, m)$  where  $\vec{V}$  is the vector of parties with corresponding public keys  $\vec{v}$ ,  $\mathcal{O}_{SK}$  was not queried on input  $A_i$ , and  $\mathcal{O}_{RK}$  was not queried on input  $B_j$ . The advantage of  $\mathbf{A}$  in winning the Unforgeability game is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Unforg}}$  as described above, and is denoted  $\text{Adv}^{\text{Unforg}}(\mathbf{A})$ .

We say that an adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Correctness, Consistency, or Unforgeability of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n_S$  different senders, queries  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n_R$  different receivers, makes at most  $q_E$  and  $q_D$  queries to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, with the sum of lengths of the party vectors input to  $\mathcal{O}_E$  being at most  $d_E$ , and  $\mathbf{A}$ 's advantage in winning the (corresponding) security game is at least  $\varepsilon$ .

**6.1.1 New (IND + IK)-CCA-2<sup>adap</sup> and Off-The-Record Notions.** Analogously to Section 4.1.1, in this section we present the new enhanced OTR and (IND + IK)-CCA-2<sup>adap</sup> security notions for MDRS-PKE schemes. As already mentioned, the main difference between our new notions and existing ones (see [17]) is that in our new notions the adversary can query for the secret key of any sender (see Definitions 12 and 13) and can corrupt parties adaptively.

The games defined by these notions provide adversaries with access to the oracles from before as well as to the oracles  $\mathcal{O}_E$  and  $\mathcal{O}_D$  defined below:

**Encryption Oracle:**  $\mathcal{O}_E((A_{i,0}, \vec{V}_0, m_0), (A_{i,1}, \vec{V}_1, m_1))$

1. For game system  $\mathbf{G}_{\mathbf{b}}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}$ , encrypt  $m_{\mathbf{b}}$  under  $\text{ssk}_{i,\mathbf{b}}$  ( $A_{i,\mathbf{b}}$ 's sender secret key) and  $\vec{v}_{\mathbf{b}}$  ( $\vec{V}_{\mathbf{b}}$ 's corresponding vector of receiver public keys); output  $c$ .

**Decryption Oracle:**  $\mathcal{O}_D(B_j, c)$

1. If  $c$  was the output of some query to  $\mathcal{O}_E$ , output **test**;
2. Otherwise, compute  $(\text{spk}_i, \vec{v}, m) \leftarrow D_{\text{pp},\text{sk}_j}(c)$ , where  $\text{sk}_j$  is  $B_j$ 's secret key; output  $(\text{spk}_i, \vec{v}, m)$ .

**Definition 12 ((IND + IK)-CCA-2<sup>adap</sup> Security).** For  $\mathbf{b} \in \{0, 1\}$ , game system  $\mathbf{G}_{\mathbf{b}}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if it outputs a guess bit  $b'$  with  $b' = \mathbf{b}$  and for every query  $\mathcal{O}_E((A_{i,0}, \vec{V}_0, m_0), (A_{i,1}, \vec{V}_1, m_1))$ : 1.  $|m_0| = |m_1|$ ; 2.  $|\vec{V}_0| = |\vec{V}_1|$ ; and 3. there is no query to  $\mathcal{O}_{RK}$  on any  $B_j \in \text{Set}(\vec{V}_0) \cup \text{Set}(\vec{V}_1)$  at any point during the game. We define the advantage of  $\mathbf{A}$  in winning the (IND + IK)-CCA-2<sup>adap</sup> game as

$$\text{Adv}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}} = \text{win}] + \Pr[\mathbf{AG}_1^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}} = \text{win}] - 1 \right|.$$

An adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks the  $(n_R, d_E, q_E, q_D)$ -(IND + IK)-CCA-2<sup>adap</sup> security of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n_R$  different receivers, makes at most  $q_E$  and  $q_D$  queries to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, with the sum of lengths of the party vectors input to  $\mathcal{O}_E$  being at most  $d_E$ , and satisfies  $\text{Adv}^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) \geq \varepsilon$ .

The following notion defines two game systems,  $\mathbf{G}_0^{\text{OTR}}$  and  $\mathbf{G}_1^{\text{OTR}}$ , which provide adversaries with access to an oracle  $\mathcal{O}_E$ , whose behavior varies depending on the underlying game system. For  $\mathbf{b} \in \{0, 1\}$ ,  $\mathcal{O}_E$  behaves as follows:

**Encryption Oracle:**  $\mathcal{O}_E(\text{type} \in \{\text{sig}, \text{sim}\}, A_i, \vec{V}, m, \mathcal{C})$

For game system  $\mathbf{G}_b^{\text{OTR}}$ , the oracle behaves as follows:

1. Let  $\vec{v} = (v_1, \dots, v_{|\vec{V}|})$  and  $\vec{s} = (s_1, \dots, s_{|\vec{V}|})$ , where, for  $i \in \{1, \dots, |\vec{V}|\}$ :
 
$$- (v_i, s_i) = \begin{cases} \mathcal{O}_{RK}(V_i) & \text{if } V_i \in \mathcal{C} \\ (\mathcal{O}_{RPK}(V_i), \perp) & \text{otherwise;} \end{cases}$$
2.  $(c_0, c_1) \leftarrow (\Pi.E_{\text{pp}}(\text{ssk}_i, \vec{v}, m), \Pi.Forge_{\text{pp}}(\text{spk}_i, \vec{v}, m, \vec{s}))$ ;
3. If  $b = 0$ , output  $c_0$  if  $\text{type} = \text{sig}$  and  $c_1$  if  $\text{type} = \text{sim}$ ; otherwise, if  $b = 1$ , output  $c_1$ .

**Definition 13 (Off-The-Record).** For  $b \in \{0, 1\}$ , game system  $\mathbf{G}_b^{\text{OTR}}$  provides an adversary  $\mathbf{A}$  with access to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ .  $\mathbf{A}$  wins the game if it outputs a guess bit  $b'$  with  $b' = b$  and for every query  $(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  to  $\mathcal{O}_E$ , and letting  $c$  be the output of  $\mathcal{O}_E$ , all of the following hold: 1.  $\mathcal{C} \subseteq \text{Set}(\vec{V})$ ; 2. for every query  $B_j$  to  $\mathcal{O}_{VK}$ ,  $B_j \notin \text{Set}(\vec{V}) \setminus \mathcal{C}$ ; 3. for all queries  $\mathcal{O}_D(B_j, c')$ ,  $c' \neq c$ .  $\mathbf{A}$ 's advantage in winning the Off-The-Record security game is

$$Adv^{\text{OTR}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{\text{OTR}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{OTR}} = \text{win}] - 1 \right|.$$

We say that an adversary  $\mathbf{A}$   $(\varepsilon_{\text{OTR}}, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Off-The-Record security of  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n_S$  different senders, queries  $\mathcal{O}_{RK}$ ,  $\mathcal{O}_{RPK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n_R$  different receivers, makes at most  $q_E$  and  $q_D$  queries to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, with the sum of lengths of the party vectors input to  $\mathcal{O}_E$  being at most  $d_E$ , and satisfies  $Adv^{\text{OTR}}(\mathbf{A}) \geq \varepsilon_{\text{OTR}}$ . Finally, we say that  $\Pi$  is

$$(\varepsilon_{\text{Corr}}, \varepsilon_{\text{Cons}}, \varepsilon_{\text{Unforg}}, \varepsilon_{(\text{IND}+\text{IK})\text{-CCA-2}^{\text{adap}}}, \varepsilon_{\text{OTR}}, \\ t, n_S, n_R, d_E, q_E, q_D)\text{-secure,}$$

if no adversary  $\mathbf{A}$ : 1.  $(\varepsilon_{\text{Corr}}, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Correctness of  $\Pi$ ; 2.  $(\varepsilon_{\text{Cons}}, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Consistency of  $\Pi$ ; 3.  $(\varepsilon_{\text{Unforg}}, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Unforgeability of  $\Pi$ ; 4.  $(\varepsilon_{(\text{IND}+\text{IK})\text{-CCA-2}^{\text{adap}}}, t)$ -breaks the  $(n_R, d_E, q_E, q_D)$ - $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security of  $\Pi$ ; or 5.  $(\varepsilon_{\text{OTR}}, t)$ -breaks the  $(n_S, n_R, d_E, q_E, q_D)$ -Off-The-Record security of  $\Pi$ .

## 6.2 Construction of MDRS-PKE with Short Ciphertexts

Maurer et al. give a black-box construction of an MDRS-PKE scheme from a PKEBC scheme and an MDVS scheme [17]. At a high level, the construction [17, Algorithm 2] essentially relies on the MDVS scheme to sign messages, and on the PKEBC scheme to encrypt the message, the signature and all relevant public keys. More concretely, in their construction a sender key-pair consists of an MDVS signer key-pair, whereas a receiver key-pair consists of an MDVS verifier key-pair and a PKEBC key-pair. To encrypt a message  $m$ , a signer first uses its

MDVS signer key-pair to generate a signature  $\sigma$  on both  $m$  and the vector of PKEBC public keys of the intended receivers, and then uses the PKEBC scheme to encrypt its own MDVS signer public key, the MDVS verifier public key of each receiver, the message  $m$  and the signature  $\sigma$ ; the resulting MDRS-PKE ciphertext is the one output by the PKEBC scheme. Conversely, to decrypt an MDRS-PKE ciphertext, a receiver first decrypts the PKEBC ciphertext, obtaining not only the vector of PKEBC public keys of the receivers, but also a signer’s MDVS public key (of the sender), a vector of MDVS verifier public keys (of each of the receivers), a message  $m$ , and an MDVS signature  $\sigma$ ; then, it uses its MDVS secret verification key to check if  $\sigma$  is a valid MDVS signature on the message  $m$  and the vector of PKEBC public keys obtained from decryption, and with respect to all the MDVS public keys obtained from decrypting the PKEBC ciphertext.

*Security of the Resulting MDRS-PKE Scheme.* In contrast to the MDRS-PKE security notions considered in this paper, the original notions introduced in [17] do not capture the setting where the adversary is given access to the secret keys of signers (see [17, Definitions 9, 10 and 11]). Yet, as noted by the authors, on one hand the IND-CCA-2 and IK-CCA-2 security proofs of the MDRS-PKE construction (see [18, Sections H.2 and H.3]) actually prove the scheme’s security with respect to the stronger IND-CCA-2 and IK-CCA-2 security notions where the adversary is given access to any sender secret keys. On the other hand, and as is even noted by the authors in [17, Remark 11], if one would assume the underlying MDVS scheme satisfies the stronger off-the-record notion we consider in this paper—wherein the adversary is given access to the sender’s secret key, see Definition 4—then the resulting MDRS-PKE scheme also satisfies the corresponding stronger off-the-record notion (that we also consider in this paper, see Definition 13).

Regarding adaptive security, note that the only security notions from [17] where the adversary cannot adaptively corrupt parties are the IND-CCA-2 and IK-CCA-2 security notions (see [17, Definitions 9 and 10]). Yet, the MDRS-PKE construction’s IND-CCA-2 security proof (see [18, Section H.2]) is a trivial reduction to the IND-CCA-2 security of the underlying PKEBC scheme, and the IK-CCA-2 security proof (see [18, Section H.3]) is also a trivial reduction, but to both the IND-CCA-2 and IK-CCA-2 security of the underlying PKEBC scheme (this is necessary since the PKEBC is used to encrypt the MDVS public keys of the involved parties). It is then rather straightforward to see that the IND-CCA-2 and IK-CCA-2 security proofs from [18] can be trivially adapted for the case of adaptive corruptions, as long as one assumes that the underlying PKEBC scheme is also secure with respect to adaptive corruptions. In fact, and since, as one may note, we consider the joint  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security notions (see Definitions 8 and 12) that capture both  $\text{IND-CCA-2}^{\text{adap}}$  and  $\text{IK-CCA-2}^{\text{adap}}$ , the MDRS-PKE scheme’s  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security proof becomes even simpler: it essentially becomes a one to one reduction to the  $(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}$  security of the underlying PKEBC scheme.

## Appendix

### A Game-Based Security Definitions

#### A.1 One Way Function Schemes

A One Way Function (OWF)  $\Pi$  is a pair  $\Pi = (S, F)$ , where  $S$  is a Probabilistic Polynomial Time Algorithm (PPT) and  $F$  is a Polynomial Time Algorithm (PT). The role of  $S$  is sampling values from  $F$ 's domain, whereas the role of  $F$  is to actually compute the function. Definition 14, which captures the security of OWF schemes, makes use of oracles  $\mathcal{O}_Y$  and  $\mathcal{O}_S$ , which, for an OWF  $\Pi = (S, F)$  are defined as:

**Image Generation Oracle:**  $\mathcal{O}_Y(i \in \mathbb{N})$

1. On the first call on index  $i \in \mathbb{N}$ , compute  $x \leftarrow S(1^k)$  and store  $(i, x, y := F(x))$ ; output  $y$ ;
2. On subsequent calls, simply output  $y$ .

**Submission Oracle:**  $\mathcal{O}_S(i \in \mathbb{N}, x)$

1. On the first call on  $i$  (to either this oracle or to  $\mathcal{O}_Y$ ), compute  $x \leftarrow S(1^k)$  and store  $(i, x, y := F(x))$ ; the oracle does not give any output;
2. On subsequent calls, the oracle simply does not perform any action nor give any output.

**Definition 14.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}^{\text{OWF}}$ :

1.  $\mathbf{A}^{\mathcal{O}_Y, \mathcal{O}_S}$ .

$\mathbf{A}$  wins the game if it makes a query to  $\mathcal{O}_S$  on an input  $(i, x)$  such that  $F(x) = \mathcal{O}_Y(i)$ .

$\mathbf{A}$ 's advantage in winning the One Way Function security game is defined as

$$\text{Adv}^{\text{OWF}}(\mathbf{A}) := \Pr[\mathbf{A}\mathbf{G}^{\text{OWF}} = \text{win}].$$

An adversary  $\mathbf{A}$   $(\varepsilon_{\text{OWF}}, t)$ -breaks the  $(n)$ -One-Wayness of OWF  $\Pi$  if it runs in time  $t$ , queries oracles  $\mathcal{O}_Y$  and  $\mathcal{O}_S$  on at most  $n$  different indices  $i \in \mathbb{N}$ , and satisfies  $\text{Adv}^{\text{OWF}}(\mathbf{A}) \geq \varepsilon_{\text{OWF}}$ . We say  $\Pi$  is  $(\varepsilon_{\text{OWF}}, t, n)$ -secure if there is no such adversary.

#### A.2 Public Key Encryption Schemes

A Public Key Encryption (PKE) scheme  $\Pi$  with message space  $\mathcal{M}$  is a triple of PPTs  $\Pi = (G, E, D)$ . Below we state the multi-user multi-challenge variants of Correctness and IND-CPA and IK-CPA security for PKE schemes (first introduced in [9] and [3], respectively). Throughout the rest of this section, let  $\Pi = (G, E, D)$  be a PKE scheme with message space  $\mathcal{M}$ . As before, we assume the game systems of the following definitions have (an implicitly defined) security parameter  $k$ .

Definition 15, which captures the correctness of PKE schemes, provides adversaries with access to oracles  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$ :

**Secret Key Generation Oracle:**  $\mathcal{O}_{SK}(B_j)$

1. On the first call on  $B_j$ , compute and store  $(\mathbf{pk}_j, \mathbf{sk}_j) \leftarrow G(1^k)$ ; output  $(\mathbf{pk}_j, \mathbf{sk}_j)$ ;
2. On subsequent calls, simply output  $(\mathbf{pk}_j, \mathbf{sk}_j)$ .

**Public Key Generation Oracle:**  $\mathcal{O}_{PK}(B_j)$

1.  $(\mathbf{pk}_j, \mathbf{sk}_j) \leftarrow \mathcal{O}_{SK}(B_j)$ ; output  $\mathbf{pk}_j$ .

**Encryption Oracle:**  $\mathcal{O}_E(B_j, m; r)$

1. If  $r$  is given as input, encrypt  $m$  under  $\mathbf{pk}_j$  ( $B_j$ 's public key, as generated by  $\mathcal{O}_{PK}$ ) using  $r$  as random tape; if  $r$  is not given as input create a fresh encryption of  $m$  under  $\mathbf{pk}_j$ ;
2. Output the resulting ciphertext back to the adversary.

**Decryption Oracle:**  $\mathcal{O}_D(B_j, c)$

1. Decrypt  $c$  using  $\mathbf{sk}_j$  ( $B_j$ 's secret key, as generated by  $\mathcal{O}_{PK}$ );
2. Output the resulting plaintext back to the adversary (or  $\perp$  if decryption failed).

**Definition 15.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}^{\text{Corr}}$ :

$$- \mathbf{A}^{\mathcal{O}_{SK}, \mathcal{O}_{PK}, \mathcal{O}_E, \mathcal{O}_D}$$

$\mathbf{A}$  wins the game if there are two queries  $q_E$  and  $q_D$  to  $\mathcal{O}_E$  and  $\mathcal{O}_D$ , respectively, where  $q_E$  has input  $(B_j, m; r)$  and  $q_D$  has input  $(B_j', c)$ , the input  $c$  in  $q_D$  is the output of  $q_E$ ,  $B_j = B_j'$ , and the output of  $q_D$  is not  $m$ .

The advantage of  $\mathbf{A}$  in winning the Correctness game, denoted  $\text{Adv}^{\text{Corr}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Corr}}$  as described above.

A (computationally unbounded) adversary  $\mathbf{A}$  ( $\varepsilon_{\text{Corr}}$ )-breaks the ( $n$ )-Correctness of a PKE scheme  $\Pi$  if  $\mathbf{A}$  queries  $\mathcal{O}_{PK}$ ,  $\mathcal{O}_E$  and  $\mathcal{O}_D$  on at most  $n$  different parties and satisfies  $\text{Adv}^{\text{Corr}}(\mathbf{A}) \geq \varepsilon_{\text{Corr}}$ .

The IND-CPA game systems provide adversaries with access to oracle  $\mathcal{O}_{PK}$  described above, and to an additional oracle  $\mathcal{O}_E$  which behaves as follows:

**Encryption Oracle:**  $\mathcal{O}_E(B_j, m_0, m_1)$

1. For game system  $\mathbf{G}_{\mathbf{b}}^{\text{IND-CPA}}$ , the oracle encrypts  $m_{\mathbf{b}}$  under  $B_j$ 's public key,  $\mathbf{pk}_j$ , creating a fresh ciphertext  $c$ ;
2. The oracle outputs the resulting ciphertext  $c$  back to the adversary.

**Definition 16.** For  $\mathbf{b} \in \{0, 1\}$ , consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}_{\mathbf{b}}^{\text{IND-CPA}}$ :

$$- b' \leftarrow \mathbf{A}^{\mathcal{O}_{PK}, \mathcal{O}_E}$$

$\mathbf{A}$  wins the game if  $b' = \mathbf{b}$  and for every query  $\mathcal{O}_E(B_j, m_0, m_1)$ ,  $|m_0| = |m_1|$ .

We define the advantage of  $\mathbf{A}$  in winning the IND-CPA security game as

$$\text{Adv}^{\text{IND-CPA}}(\mathbf{A}) := \left| \Pr[\mathbf{A}\mathbf{G}_0^{\text{IND-CPA}} = \text{win}] + \Pr[\mathbf{A}\mathbf{G}_1^{\text{IND-CPA}} = \text{win}] - 1 \right|.$$

Similarly to the IND-CPA game systems, the IK-CPA game systems provide adversaries with access to oracle  $\mathcal{O}_{PK}$  and to an oracle  $\mathcal{O}_E$  which behaves as follows:

**Encryption Oracle:**  $\mathcal{O}_E(B_{j,0}, B_{j,1}, m)$

1. For game system  $\mathbf{G}_{\mathbf{b}}^{\text{IK-CPA}}$ , encrypt  $m$  under  $B_{j,\mathbf{b}}$ 's public key,  $\text{pk}_{j,\mathbf{b}}$ , creating a fresh ciphertext  $c$ ;
2. Output the resulting ciphertext  $c$  back to the adversary.

**Definition 17.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}_{\mathbf{b}}^{\text{IK-CPA}}$ , with  $\mathbf{b} \in \{0, 1\}$ :

–  $b' \leftarrow \mathbf{A}^{\mathcal{O}_{PK}, \mathcal{O}_E}$

$\mathbf{A}$  wins the game if  $b' = \mathbf{b}$ .

We define the advantage of  $\mathbf{A}$  in winning the IK-CPA security game as

$$\text{Adv}^{\text{IK-CPA}}(\mathbf{A}) := \left| \Pr[\mathbf{A}\mathbf{G}_0^{\text{IK-CPA}} = \text{win}] + \Pr[\mathbf{A}\mathbf{G}_1^{\text{IK-CPA}} = \text{win}] - 1 \right|.$$

We say  $\mathbf{A}$  ( $\varepsilon_{\text{IND-CPA}}, t$ )-breaks (resp. ( $\varepsilon_{\text{IK-CPA}}, t$ )-breaks) the  $(n, q_E)$ -IND-CPA (resp.  $(n, q_E)$ -IK-CPA) security of a PKE scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , queries the oracles it has access to on at most  $n$  different parties, makes at most  $q_E$  queries to oracle  $\mathcal{O}_E$ , and satisfies  $\text{Adv}^{\text{IND-CPA}}(\mathbf{A}) \geq \varepsilon_{\text{IND-CPA}}$  (resp.  $\text{Adv}^{\text{IK-CPA}}(\mathbf{A}) \geq \varepsilon_{\text{IK-CPA}}$ ).

Finally,  $\Pi$  is  $(\varepsilon_{\text{Corr}}, \varepsilon_{\text{IND-CPA}}, \varepsilon_{\text{IK-CPA}}, t, n, q_E)$ -secure if no adversary  $\mathbf{A}$  ( $\varepsilon_{\text{IND-CPA}}, t$ )-breaks the  $(n, q_E)$ -IND-CPA security of  $\Pi$  nor ( $\varepsilon_{\text{IK-CPA}}, t$ )-breaks the  $(n, q_E)$ -IK-CPA security of  $\Pi$ , and no (possibly computationally unbounded) adversary ( $\varepsilon_{\text{Corr}}$ )-breaks the  $(n)$ -Correctness of  $\Pi$ .

### A.3 Symmetric Encryption Schemes

A Symmetric Encryption (SKE) scheme  $\Pi$  with message space  $\mathcal{M}$  is a triple of PPTs  $\Pi = (G, E, D)$ . Below we state the (Perfect) Correctness notion and the IND-CPA security notion for SKE schemes. Throughout the rest of this section, let  $\Pi = (G, E, D)$  be an SKE scheme. As before, we assume the game systems of the following definitions have (an implicitly defined) security parameter  $k$ .

**Definition 18.** Consider a SKE scheme  $\Pi = (G, E, D)$  with message space  $\mathcal{M}$ . We say  $\Pi$  is correct if for every  $m \in \mathcal{M}$  and every key  $k_{\text{sym}} \in \text{Supp}(G(1^k))$ :

$$\Pr[D(k_{\text{sym}}, E(k_{\text{sym}}, m)) = m] = 1.$$

The (One Time) 1-IND-CPA game systems provide adversaries with access to oracle  $\mathcal{O}_K$  described above, and to an additional oracle  $\mathcal{O}_E$  which behaves as follows:

**Encryption Oracle:**  $\mathcal{O}_E(i \in \mathbb{N}, m_0, m_1)$

1. For game system  $\mathbf{G}_{\mathbf{b}}^{1\text{-IND-CPA}}$ , the oracle encrypts  $m_{\mathbf{b}}$  under the  $i$ -th key,  $\mathbf{k}_i$ , creating a fresh ciphertext  $c$ ;

2. The oracle outputs the resulting ciphertext  $c$ .

**Definition 19.** For  $\mathbf{b} \in \{0, 1\}$ , consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}_{\mathbf{b}}^{1\text{-IND-CPA}}$ :

–  $b' \leftarrow \mathbf{A}^{\mathcal{O}_E}$

$\mathbf{A}$  wins the game if  $b' = \mathbf{b}$  and for every query  $\mathcal{O}_E(i, m_0, m_1)$ ,  $|m_0| = |m_1|$  and there is no other query to  $\mathcal{O}_E$  on the same index  $i$ .

$\mathbf{A}$ 's advantage in winning the (One Time) 1-IND-CPA security game is defined as

$$\text{Adv}^{1\text{-IND-CPA}}(\mathbf{A}) := \left| \Pr[\mathbf{A}\mathbf{G}_0^{1\text{-IND-CPA}} = \text{win}] + \Pr[\mathbf{A}\mathbf{G}_1^{1\text{-IND-CPA}} = \text{win}] - 1 \right|.$$

We say  $\mathbf{A}$   $(\varepsilon_{1\text{-IND-CPA}}, t)$ -breaks the  $(q_E)$ -1-IND-CPA security of an SKE scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , makes at most  $q_E$  queries to oracle  $\mathcal{O}_E$  and satisfies  $\text{Adv}^{1\text{-IND-CPA}}(\mathbf{A}) \geq \varepsilon_{1\text{-IND-CPA}}$ .

Finally, we say  $\Pi$  is  $(\varepsilon_{1\text{-IND-CPA}}, t, q_E)$ -secure if  $\Pi$  is perfectly correct (see Definition 18) and no adversary  $\mathbf{A}$   $(\varepsilon_{1\text{-IND-CPA}}, t)$ -breaks the  $(q_E)$ -1-IND-CPA security of  $\Pi$ .

#### A.4 Non Interactive Zero Knowledge Schemes

For a binary relation  $R$ , let  $L_R$  be the language  $L_R := \{x \mid \exists w, (x, w) \in R\}$  induced by  $R$ . A *Non Interactive Proof System* (NIPS) for  $L_R$  is a triple of PPT algorithms  $\Pi = (G_{CRS}, \text{Prove}, \text{Verify})$  where:

- $G_{CRS}(1^k)$ : given security parameter  $1^k$ , outputs a common reference string **crs**;
- $\text{Prove}_{\text{crs}}(x, w)$ : given a common reference string **crs** and a statement-witness pair  $(x, w) \in R$ , outputs a proof  $p$ ;
- $\text{Verify}_{\text{crs}}(x, p)$ : given a common reference string **crs**, a statement  $x$  and a proof  $p$ , either accepts, outputting **valid** ( $= 1$ ) or rejects, outputting **invalid** ( $= 0$ ).

In the following definitions, let  $\Pi = (G_{CRS}, \text{Prove}, \text{Verify})$  be a NIPS for a relation  $R$ , and let  $k$  be the security parameter. The security notions below (Definitions 20 and 21) provide adversaries with access to oracles  $\mathcal{O}_S$  and  $\mathcal{O}_V$ , defined as:

**CRS Generation Oracle:**  $\mathcal{O}_S$

1. On the first call, compute and store  $\text{crs} \leftarrow G_{CRS}(1^k)$ ; output **crs**;
2. On subsequent calls, output the previously generated **crs**.

**Verify Oracle:**  $\mathcal{O}_V(x, p)$

1. Compute  $b = \text{Verify}_{\text{crs}}(x, p)$ ; output  $b$ .

Definition 20 additionally provides adversaries with access to an oracle  $\mathcal{O}_P$ :

**Prove Oracle:**  $\mathcal{O}_P(x, w)$

1. Compute  $p = \text{Prove}_{\text{crs}}(x, w)$ ; output  $p$ .

**Definition 20.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}^{\text{Complete}}$ :

- $\mathbf{A}^{\mathcal{O}_S, \mathcal{O}_P, \mathcal{O}_V}$

$\mathbf{A}$  wins the game if there are two queries  $q_P$  and  $q_V$  to  $\mathcal{O}_P$  and  $\mathcal{O}_V$ , respectively, where  $q_P$  has input  $(x, w)$  and  $q_V$  has input  $(x', p)$ , satisfying  $x = x'$ , the input  $p$  in  $q_V$  is the output of  $q_P$ , the output of  $q_V$  is **invalid**, and  $(x, w) \in R$ .

The advantage of  $\mathbf{A}$  in winning the Completeness game, denoted  $\text{Adv}^{\text{Complete}}(\mathbf{A})$ , corresponds to the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Complete}}$  as described above.

We say that an adversary  $\mathbf{A}$   $(\varepsilon^{\text{Complete}}, t)$ -breaks the  $(q_P, q_V)$ -Completeness of a NIPS scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , makes at most  $q_P$  and  $q_V$  queries to oracles  $\mathcal{O}_P$  and  $\mathcal{O}_V$ , respectively, and satisfies  $\text{Adv}^{\text{Complete}}(\mathbf{A}) \geq \varepsilon^{\text{Complete}}$ .

**Definition 21.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}^{\text{Sound}}$ :

- $\mathbf{A}^{\mathcal{O}_S, \mathcal{O}_V}$

$\mathbf{A}$  wins the game if there is a query to  $\mathcal{O}_V$  on input  $(x, p)$ , satisfying  $x \notin L_R$ , such that the oracle outputs **valid**.

The advantage of  $\mathbf{A}$  in winning the Soundness game corresponds to the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{Sound}}$  as described above and is denoted  $\text{Adv}^{\text{Sound}}(\mathbf{A})$ .

An adversary  $\mathbf{A}$   $(\varepsilon^{\text{Sound}}, t)$ -breaks the  $(q_V)$ -Soundness of a NIPS scheme  $\Pi$  if  $\mathbf{A}$  runs in time at most  $t$ , makes at most  $q_V$  queries to  $\mathcal{O}_V$  and satisfies  $\text{Adv}^{\text{Sound}}(\mathbf{A}) \geq \varepsilon^{\text{Sound}}$ .

A NIZK scheme  $\Pi = (G_{\text{CRS}}, \text{Prove}, \text{Verify}, S = (S_{\text{CRS}}, S_{\text{Sim}}))$  for a relation  $R$  consists of a NIPS scheme  $\Pi' = (G_{\text{CRS}}, \text{Prove}, \text{Verify})$  for  $R$  and a simulator  $S = (S_{\text{CRS}}, S_{\text{Sim}})$ , where:

- $S_{\text{CRS}}(1^k)$ : given security parameter  $1^k$ , outputs a pair  $(\text{crs}, \tau)$ ;
- $S_{\text{Sim}(\text{crs}, \tau)}(x)$ : given a pair  $(\text{crs}, \tau)$  and a statement  $x$ , outputs a proof  $p$ .

Consider a NIZK scheme  $\Pi = (G_{\text{CRS}}, \text{Prove}, \text{Verify}, S = (S_{\text{CRS}}, S_{\text{Sim}}))$ . The following security notion, which defines game systems  $\mathbf{G}_0^{\text{ZK}}$  and  $\mathbf{G}_1^{\text{ZK}}$ , provides adversaries with access to two oracles,  $\mathcal{O}_S$  and  $\mathcal{O}_P$ , whose behavior depends on the underlying game system. For  $\mathbf{G}_b^{\text{ZK}}$  (with  $b \in \{0, 1\}$ ):

**CRS Generation Oracle:**  $\mathcal{O}_S$

1. On the first call, compute and store  $\text{crs} \leftarrow G_{\text{CRS}}(1^k)$  if  $\mathbf{b} = \mathbf{0}$ , and  $(\text{crs}, \tau) \leftarrow S_{\text{CRS}}(1^k)$  if  $\mathbf{b} = \mathbf{1}$ ; output  $\text{crs}$ ;
2. On subsequent calls, output the previously generated  $\text{crs}$ .

**Prove Oracle:**  $\mathcal{O}_P(x, w)$

- If  $\mathbf{b} = \mathbf{0}$ , output  $\pi = \text{Prove}_{\text{crs}}(x, w)$ ;
- If  $\mathbf{b} = \mathbf{1}$ , output  $\pi \leftarrow S_{\text{Sim}(\text{crs}, \tau)}(x)$ .

**Definition 22.** For  $\mathbf{b} \in \{0, 1\}$ , consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}_{\mathbf{b}}^{\text{ZK}}$ :

–  $b' \leftarrow \mathbf{A}^{\mathcal{O}_S, \mathcal{O}_P}$

$\mathbf{A}$  wins the game if  $b' = \mathbf{b}$  and for every query to  $\mathcal{O}_P$ , the input  $(x, w)$  given to  $\mathcal{O}_P$  satisfies  $(x, w) \in R$ .

The advantage of  $\mathbf{A}$  in winning the Zero-Knowledge security game for  $\Pi$  is

$$\text{Adv}^{\text{ZK}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{\text{ZK}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{ZK}} = \text{win}] - 1 \right|.$$

We say that an adversary  $\mathbf{A}$   $(\varepsilon_{\text{ZK}}, t)$ -breaks the  $(q_P)$ -ZK security of a NIZK scheme  $\Pi$  if it makes at most  $q_P$  queries to  $\mathcal{O}_P$  and satisfies  $\text{Adv}^{\text{ZK}}(\mathbf{A}) \geq \varepsilon_{\text{ZK}}$ .

We now introduce Simulation Soundness for NIZK [21]. The game system defined by this notion provides adversaries with access to oracles  $\mathcal{O}_S$ ,  $\mathcal{O}_P$  and  $\mathcal{O}_V$  defined as:

**CRS Generation Oracle:**  $\mathcal{O}_S$

1. On the first call, compute and store  $(\text{crs}, \tau) \leftarrow S_{\text{CRS}}(1^k)$ ; output  $\text{crs}$ ;
2. On subsequent calls, output the previously generated  $\text{crs}$ .

**Prove Oracle:**  $\mathcal{O}_P(x)$

1. Compute  $p = S_{\text{Sim}(\text{crs}, \tau)}(x)$ ; output  $p$ .

**Verify Oracle:**  $\mathcal{O}_V(x, p)$

1. Compute  $b = \text{Verify}_{\text{crs}}(x, p)$ ; output  $b$ .

**Definition 23.** Consider the following game played between an adversary  $\mathbf{A}$  and game system  $\mathbf{G}^{\text{SS}}$ :

–  $\mathbf{A}^{\mathcal{O}_S, \mathcal{O}_P, \mathcal{O}_V}$

$\mathbf{A}$  wins the game if it makes a query to  $\mathcal{O}_V$  on input  $(x, p)$  such that  $p$  was not output by any query to  $\mathcal{O}_P$ ,  $x \notin L_R$  and  $\mathcal{O}_V$  outputs **valid**.

The advantage of  $\mathbf{A}$  in winning the Simulation Soundness game, denoted  $\text{Adv}^{\text{SS}}(\mathbf{A})$ , is the probability that  $\mathbf{A}$  wins game  $\mathbf{G}^{\text{SS}}$  as described above.

An adversary  $\mathbf{A}$   $(\varepsilon_{\text{SS}}, t)$ -breaks the  $(q_P, q_V)$ -Simulation Soundness of a NIZK scheme  $\Pi$  if it makes at most  $q_P$  and  $q_V$  queries to  $\mathcal{O}_P$  and  $\mathcal{O}_V$ , respectively, and satisfies  $\text{Adv}^{\text{SS}}(\mathbf{A}) \geq \varepsilon_{\text{SS}}$ .

Finally, we say that a NIZK scheme  $\Pi$  is  $(\varepsilon_{\text{Complete}}, \varepsilon_{\text{Sound}}, \varepsilon_{\text{ZK}}, \varepsilon_{\text{SS}}, t, q_P, q_V)$ -secure if no adversary  $\mathbf{A}$   $(\varepsilon_{\text{Complete}}, t)$ -breaks the  $(q_P, q_V)$ -Completeness of  $\Pi$ ,  $(\varepsilon_{\text{Sound}}, t)$ -breaks the  $(q_V)$ -Soundness of  $\Pi$ ,  $(\varepsilon_{\text{ZK}}, t)$ -breaks the  $(q_P)$ -Zero-Knowledge of  $\Pi$ , or  $(\varepsilon_{\text{SS}}, t)$ -breaks the  $(q_P, q_V)$ -Simulation Soundness of  $\Pi$ .

## B Full Proofs

### B.1 Helper Claims

We now establish two (straightforward) results that allow to simplify the MDVS and PKEBC security proofs ahead.

### B.1.1 One Way Function Image Collision Resistance

**Definition 24** ( *$n$ -Instance  $\varepsilon$ -Image Collision-Resistance*). A OWF  $\Pi = (S, F)$  is  $n$ -Instance  $\varepsilon$ -Image Collision-Resistant if

$$\Pr \left[ \left| \{ \Pi.F(x_1), \dots, \Pi.F(x_n) \} \right| < n \left| \begin{array}{l} x_1 \leftarrow \Pi.S(1^k) \\ \dots \\ x_n \leftarrow \Pi.S(1^k) \end{array} \right. \right] \leq \varepsilon.$$

**Lemma 1.** If  $\Pi$  is  $(\varepsilon_{\text{OWF}}, t, n)$ -secure, with  $t \gtrsim n \cdot (t_S + t_F)$ —where  $t_S$  and  $t_F$  are, respectively, the times to run  $S$  and  $F$ —then  $\Pi$  is  $n$ -Instance  $\varepsilon$ -Image Collision-Resistant, with  $\varepsilon \leq 2 \cdot \varepsilon_{\text{OWF}}$ .

*Proof.* To prove this result we give an adversary  $\mathbf{A}^n$  such that  $2 \cdot \text{Adv}^{\text{OWF}}(\mathbf{A}^n) \geq \varepsilon$ . Since  $\text{Adv}^{\text{OWF}}(\mathbf{A}^n) \leq \varepsilon_{\text{OWF}}$ , it then follows that  $\varepsilon \leq 2 \cdot \varepsilon_{\text{OWF}}$ .

Consider the following adversary  $\mathbf{A}^n$ . First,  $\mathbf{A}^n$  samples an  $n$  bit long vector  $\vec{b}$ , each bit being picked independently and uniformly at random. For each index  $i \in \{1, \dots, n\}$ , if  $b_i = 0$  then  $\mathbf{A}^n$  queries  $\mathcal{O}_Y$  on input  $i$ , and sets  $y_i = \mathcal{O}_Y(i)$ , and if  $b_i = 1$  then  $\mathbf{A}^n$  samples an element  $x_i$  from the domain of the one way function  $\Pi.S(1^k)$ , saves  $x_i$ , and sets  $y_i = \Pi.F(x_i)$ . If there are no two indices  $i, j \in \{1, \dots, n\}$  such that  $b_i \neq b_j$  and  $y_i = y_j$ ,  $\mathbf{A}^n$  aborts. Otherwise, for the least  $i \in \{1, \dots, n\}$  for which  $b_i = 0$  and there exists  $j \in \{1, \dots, n\}$  with  $b_j = 1$  and  $y_i = y_j$ ,  $\mathbf{A}^n$  makes a query  $\mathcal{O}_S(i, x_j)$ . Since algorithm  $F$  is deterministic, it follows that  $\Pi.F(x_j) = y_j = y_i$ , and so  $\mathbf{A}^n$  wins the game.

Note that if there are two indices  $i, j \in \{1, \dots, n\}$  with  $y_i = y_j$ , the only case where  $\mathbf{A}^n$  does not win the game is if  $b_i = b_j$ . Given this only happens with probability at most  $\frac{1}{2}$  and this event is independent from the existence of two indices  $i, j \in \{1, \dots, n\}$  such that  $y_i = y_j$ , it follows  $2 \cdot \text{Adv}^{\text{OWF}}(\mathbf{A}^n) \geq \varepsilon$ .  $\square$

### B.1.2 Public Key Collision Resistance

**Definition 25** ( *$n$ -Party  $\varepsilon$ -Public Key Collision-Resistance*). PKE scheme  $\Pi = (G, E, D)$  is  $n$ -Party  $\varepsilon$ -Public Key Collision-Resistant if

$$\Pr \left[ \left| \{ \text{pk}_1, \dots, \text{pk}_n \} \right| < n \left| \begin{array}{l} (\text{pk}_1, \text{sk}_1) \leftarrow \Pi.G(1^k) \\ \dots \\ (\text{pk}_n, \text{sk}_n) \leftarrow \Pi.G(1^k) \end{array} \right. \right] \leq \varepsilon.$$

**Lemma 2.** If  $\Pi$  is  $(\varepsilon_{\text{Corr}}, \varepsilon_{\text{IND-CPA}}, \varepsilon_{\text{IK-CPA}}, t, n, q_E)$ -secure, with  $t \gtrsim n \cdot t_G + t_D$ —where  $t_G$  and  $t_D$  are, respectively, the times to run  $\Pi.G$  and  $\Pi.D$ —then  $\Pi$  is  $n$ -Party  $\varepsilon$ -Public Key Collision-Resistant, with  $\varepsilon \leq 2 \cdot \varepsilon_{\text{IND-CPA}} + \varepsilon_{\text{Corr}}$ .

*Proof.* To prove this result we give two adversaries— $\mathbf{A}_{\text{IND-CPA}}^{n, m_0, m_1}$  for the IND-CPA security games and  $\mathbf{A}_{\text{Corr}}^{n, m_0, m_1}$  for the Correctness game—such that for these adversaries

$$2 \cdot \text{Adv}^{\text{IND-CPA}}(\mathbf{A}_{\text{IND-CPA}}^{n, m_0, m_1}) + \text{Adv}^{\text{Corr}}(\mathbf{A}_{\text{Corr}}^{n, m_0, m_1}) \geq \varepsilon.$$

Since  $Adv^{\text{IND-CPA}}(\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}) \leq \varepsilon_{\text{IND-CPA}}$  and  $Adv^{\text{Corr}}(\mathbf{A}_{\text{Corr}}^{n,m_0,m_1}) \leq \varepsilon_{\text{Corr}}$ , it then follows that  $\varepsilon \leq 2 \cdot \varepsilon_{\text{IND-CPA}} + \varepsilon_{\text{Corr}}$ .

Consider the following adversary  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  for the IND-CPA game of  $\Pi$ . First,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  samples an  $n$  bit long vector  $\vec{b}$ , each bit being picked independently and uniformly at random. Next,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  queries  $\mathcal{O}_{PK}$  on each party  $B_i$  for which  $b_i = 0$  and sets  $\text{pk}_i = \mathcal{O}_{PK}(B_i)$ . Similarly,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  samples a key pair using  $\Pi.G$  for each party  $B_i$  for which  $b_i = 1$  and sets  $(\text{pk}_i, \text{sk}_i) \leftarrow G(1^k)$  (where  $k$  is the security parameter). If there are no two indices  $i, j \in \{1, \dots, n\}$  such that  $b_i \neq b_j$  and  $\text{pk}_i = \text{pk}_j$ ,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  aborts. Otherwise, for the least  $i \in \{1, \dots, n\}$  for which  $b_i = 0$  and there exists  $j \in \{1, \dots, n\}$  with  $b_j = 1$  and  $\text{pk}_i = \text{pk}_j$ ,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  makes a query  $\mathcal{O}_E(B_i, m_0, m_1)$ ; letting  $c$  be the output of this query,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  tries decrypting  $c$  using  $\text{sk}_j$  (here,  $j$  is assumed to be the least  $j \in \{1, \dots, n\}$  such that  $b_j = 1$  and  $\text{pk}_i = \text{pk}_j$ ). Finally,  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  outputs 0 if the decryption resulted in  $m_0$ , 1 if the decryption resulted in  $m_1$ , and otherwise aborts.

The adversary  $\mathbf{A}_{\text{Corr}}^{n,m_0,m_1}$  for the Correctness game of  $\Pi$  uses oracle  $\mathcal{O}_{PK}$  to sample all the  $n$  parties' public keys. For each party  $B_i$  and each possible sequence  $r$  of random coins used by  $\Pi.E$ ,  $\mathbf{A}_{\text{Corr}}^{n,m_0,m_1}$  makes queries  $\mathcal{O}_E(B_i, m_0; r)$  and  $\mathcal{O}_E(B_i, m_1; r)$ . Letting  $c_0$  and  $c_1$  be the respective outputs of the two oracle queries above,  $\mathbf{A}_{\text{Corr}}^{n,m_0,m_1}$  makes queries  $\mathcal{O}_D(B_i, c_0)$  and  $\mathcal{O}_D(B_i, c_1)$ .

Note that if there are two parties  $B_i$  and  $B_j$  with equal public keys, the only case where  $\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}$  may not win the IND-CPA games is when either  $b_i = b_j$  or the scheme does not work correctly. Given  $\Pr[b_i = b_j] \leq \frac{1}{2}$  and the probability that the scheme does not work correctly is bounded by  $Adv^{\text{Corr}}(\mathbf{A}_{\text{Corr}}^{n,m_0,m_1})$ , it follows  $2 \cdot Adv^{\text{IND-CPA}}(\mathbf{A}_{\text{IND-CPA}}^{n,m_0,m_1}) + Adv^{\text{Corr}}(\mathbf{A}_{\text{Corr}}^{n,m_0,m_1}) \geq \varepsilon$ .  $\square$

## B.2 MDVS Construction Security Proofs

In this section we give the formal security theorems and the (corresponding) full proofs for the MDVS construction given in Section 4.4.

### B.2.1 Proof of Correctness

**Theorem 3.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E_{\text{PKE}}})\text{-secure,} \end{aligned} \tag{B.1}$$

and  $\Pi_{\text{NIZK}}$  is

$$\begin{aligned} & (\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})\text{-secure,} \end{aligned} \tag{B.2}$$

then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's

$$(n_V := n_{\text{PKE}}, q_S := q_{P_{\text{NIZK}}}, q_V := q_{V_{\text{NIZK}}})\text{-Correctness,}$$

with  $\varepsilon > \varepsilon_{\text{NIZK-Complete}} + \varepsilon_{\text{PKE-Corr}}$  and with  $t_{\text{NIZK}} \approx t + t_{\text{Corr}}$ , where  $t_{\text{Corr}}$  is the time to run  $\Pi$ 's  $\mathbf{G}^{\text{Corr}}$  game.

*Proof.* This proof proceeds in a sequence of games [4, 23].

$\mathbf{G}^{\text{Corr}} \rightsquigarrow \mathbf{G}^1$ :  $\mathbf{G}^1$  is just like the original game  $\mathbf{G}^{\text{Corr}}$ , except that in  $\mathbf{G}^1$  for each signature  $\sigma := (p, \vec{c}, c_{\text{pp}})$  output by a query  $\mathcal{O}_S(A_i, \vec{V}, m)$ , if  $\mathcal{O}_V$  is queried on any input  $(A_i', B_j, \vec{V}', m', \sigma')$  with  $(A_i, \vec{V}, m, \sigma) = (A_i', \vec{V}', m', \sigma')$  and  $B_j \in \vec{V}$ , it no longer verifies  $p$ 's validity and simply proceeds as if it were valid.

Note that one can reduce distinguishing  $\mathbf{G}^{\text{Corr}}$  and  $\mathbf{G}^1$  to breaking  $\Pi_{\text{NIZK}}$ 's completeness: since the reduction holds the secret keys of every signer and of every verifier, it can trivially handle any oracle queries. Furthermore, the reduction makes at most one  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  query for each  $\mathcal{O}_S$  query, and at most one  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  query for each  $\mathcal{O}_V$  query. Since  $\mathbf{A}$  only makes up to  $q_S \leq q_{P_{\text{NIZK}}}$  queries to  $\mathcal{O}_S$  and  $q_V \leq q_{V_{\text{NIZK}}}$  queries to  $\mathcal{O}_V$ , it follows from Equation B.2 that no adversary  $(\varepsilon_{\text{NIZK-Complete}}, t_{\text{NIZK}})$ -breaks the  $(q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})$ -Completeness of  $\Pi_{\text{NIZK}}$ , implying

$$\left| \Pr[\mathbf{AG}^1 = \text{win}] - \Pr[\mathbf{AG}^{\text{Corr}} = \text{win}] \right| \leq \varepsilon_{\text{NIZK-Complete}}.$$

$\mathbf{G}^1 \rightsquigarrow \mathbf{G}^2$ . Game  $\mathbf{G}^2$  is just like  $\mathbf{G}^1$ , except that now for each signature  $\sigma := (p, \vec{c}, c_{\text{pp}})$  output by a query  $\mathcal{O}_S(A_i, \vec{V}, m)$ , if  $\mathcal{O}_V$  is queried on any input  $(A_i', B_j, \vec{V}', m', \sigma')$ , with  $(A_i, \vec{V}, m, \sigma) = (A_i', \vec{V}', m', \sigma')$  and  $B_j \in \vec{V}$ , and letting  $l \in \{1, \dots, |\vec{V}|\}$  be the least index such that  $B_j = V_l$ ,  $\mathcal{O}_V$  no longer tries decrypting ciphertext  $c_{l,b} \in (c_{l,0}, c_{l,1})$ —where  $b$  is the secret bit in  $B_j$ 's secret key and  $(c_{l,0}, c_{l,1}) \in \vec{c}$ —and instead simply outputs 1 as if the decryption of  $c_{l,b}$  had output 1.

It is easy to see that one can reduce distinguishing these two games to breaking  $\Pi_{\text{PKE}}$ 's correctness: since the reduction holds all secret keys, it can handle any oracle queries. Noting that an adversary  $\mathbf{A}$  can only query for the verifier public keys of at most  $n_V \leq n_{\text{PKE}}$  parties and since the reduction only has to rely on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{SK}$  oracle to generate at most one key-pair per party (namely,  $(\text{pk}_b, \text{sk}_b)$ ), it follows from Equation B.1 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the  $(n_{\text{PKE}})$ -Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^2 = \text{win}] - \Pr[\mathbf{AG}^1 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

To conclude, since no adversary can win game  $\mathbf{G}^2$ ,  $\Pr[\mathbf{AG}^2 = \text{win}] = 0$ .  $\square$

## B.2.2 Proof of Consistency

**Theorem 4.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E_{\text{PKE}}})\text{-secure}, \end{aligned} \tag{B.3}$$

*with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})\text{-secure}, \end{aligned} \tag{B.4}$$

$\Pi_{\text{OWF}}$  is

$$(\varepsilon_{\text{OWF}}, t_{\text{OWF}}, n_{\text{OWF}})\text{-secure}, \quad (\text{B.5})$$

and  $\Pi_{\text{NIZK}}$ .  $V$  is a deterministic algorithm, then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's

$$(n_V := \min(n_{\text{PKE}}, n_{\text{OWF}}), q_V := q_{V_{\text{NIZK}}})\text{-Consistency},$$

with  $\varepsilon > 3 \cdot \varepsilon_{\text{PKE-Corr}} + \varepsilon_{\text{NIZK-Sound}} + 2 \cdot \varepsilon_{\text{OWF}}$  and with  $t_{\text{NIZK}}, t_{\text{OWF}} \approx t + t_{\text{Cons}}$ , where  $t_{\text{Cons}}$  is the time to run  $\Pi$ 's  $\mathbf{G}^{\text{Cons}}$  game.

*Proof.* We proceed via game hopping.

$\mathbf{G}^{\text{Cons}} \rightsquigarrow \mathbf{G}^1$ :  $\mathbf{G}^1$  is just like  $\mathbf{G}^{\text{Cons}}$  except that in  $\mathbf{G}^1$  the  $\Pi_{\text{PKE}}$  key pair  $(\text{pk}_0, \text{sk}_0)$  sampled for each party  $B_j$  is assumed to be a correct one.

Note that one can reduce distinguishing these two games to breaking  $\Pi_{\text{PKE}}$ 's correctness: since the reduction holds all secret keys it can handle any oracle queries. Furthermore, given an adversary  $\mathbf{A}$  can only query for the verifier public keys of at most  $n_V \leq n_{\text{PKE}}$  parties and given the reduction only has to rely on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{SK}$  oracle to generate at most one key-pair per party—namely,  $(\text{pk}_0, \text{sk}_0)$ —it follows from Equation B.3 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the  $(n_{\text{PKE}})$ -Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^1 = \text{win}] - \Pr[\mathbf{AG}^{\text{Cons}} = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^1 \rightsquigarrow \mathbf{G}^2$ : This game hop is just like the previous one (i.e.  $\mathbf{G}^{\text{Cons}} \rightsquigarrow \mathbf{G}^1$ ), the only difference being that the key-pair which is assumed to be a correct one is now  $(\text{pk}_1, \text{sk}_1)$ . Hence,

$$\left| \Pr[\mathbf{AG}^2 = \text{win}] - \Pr[\mathbf{AG}^1 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ : This step is similar to the previous ones, except that this time the key pair that is assumed to be a correct one is the public parameters' public key and the corresponding secret key (i.e. the key pair sampled by  $\Pi.S$ ).

One can, once again, reduce distinguishing these games to breaking  $\Pi_{\text{PKE}}$ 's correctness: the reduction has all secret keys so it can handle any oracle queries. In contrast to the previous reductions, this one only has to rely on the  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  oracle to generate a single key-pair. Since  $n_{\text{PKE}} \geq 1$ , it then follows from Equation B.3 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the (1)-Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^3 = \text{win}] - \Pr[\mathbf{AG}^2 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^3 \rightsquigarrow \mathbf{G}^4$ : Game  $\mathbf{G}^4$  is just  $\mathbf{G}^3$  except that for each query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  in  $\mathbf{G}^4$  it is assumed that if the NIZK proof  $p$  verifies as being valid then  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ .

Once again, the reduction holds all secret keys and thus it can handle any oracle query. Moreover, because the reduction has a witness for every statement it has to produce a NIZK proof for, it can simply use  $\Pi_{\text{NIZK}}.P$  to generate the NIZK proofs. Regarding  $\mathcal{O}_V$  queries, however, the reduction now relies on oracle  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  to verify the validity of each signature's the NIZK proof. Given the reduction only verifies at most one NIZK proof for each  $\mathcal{O}_V$  query and since  $q_V \leq q_{V_{\text{NIZK}}}$ , it follows from Equation B.4 that no adversary  $(\varepsilon_{\text{NIZK-Sound}}, t_{\text{NIZK}})$ -breaks the  $(q_{V_{\text{NIZK}}})$ -Soundness of  $\Pi_{\text{NIZK}}$ , and so

$$\left| \Pr[\mathbf{AG}^4 = \text{win}] - \Pr[\mathbf{AG}^3 = \text{win}] \right| \leq \varepsilon_{\text{NIZK-Sound}}.$$

To conclude we now prove the following claim:

*Claim.*  $\Pr[\mathbf{AG}^4 = \text{win}] \leq 2 \cdot \varepsilon_{\text{OWF}}$ .

*Proof.* An adversary  $\mathbf{A}$  can only win  $\mathbf{G}^4$  if it makes two queries to  $\mathcal{O}_V$  on inputs  $(A, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  and  $(A', B_{j'}, \vec{V}', m', \sigma')$  satisfying  $(A, \vec{V}, m, \sigma) = (A', \vec{V}', m', \sigma')$  and  $B_j, B_{j'} \in \vec{V}$ , and one of the queries outputs 1 while the other outputs 0.

Given  $\Pi_{\text{NIZK}}.V$  is a deterministic algorithm and one of the queries outputs 1, the NIZK proof  $p$  in the signature input to the  $\mathcal{O}_V$  queries verifies as being valid both times. Furthermore, for the least  $i, i' \in \{1, \dots, |\vec{V}|\}$  such that  $V_i = B_j$  and  $V_{i'} = B_{j'}$ , by the correctness of  $B_j$ 's and  $B_{j'}$ 's key pairs,  $c_{i,b}$  and  $c_{i',b'}$  are encryptions of two different bits— $b$  being the bit in  $B_j$ 's secret key, and  $b'$  the bit in  $B_{j'}$ 's secret key. By the soundness of  $\Pi_{\text{NIZK}}$  it follows  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ . On one hand, this implies  $c_{\text{pp}}$  is an encryption of a plaintext of the form  $(m, b'', ((b_1, x_1), \dots, (b_l, x_l)))$ , and on the other hand, since  $R_{\text{MDVS}^{\text{adap}}} \subseteq R_{\text{MDVS}^{\text{adap-Cons}}}$  and  $c_{i,b}$  and  $c_{i',b'}$  are encryptions of two different bits, either  $x_i$  is such that  $\Pi_{\text{OWF}}.F(x_i) \in \{v_i.y_0, v_i.y_1\}$  or  $x_{i'}$  is such that  $\Pi_{\text{OWF}}.F(x_{i'}) \in \{v_{i'}.y_0, v_{i'}.y_1\}$  (or both). The correctness of  $\text{pp.pk}$  implies that decrypting  $c_{\text{pp}}$  results in the plaintext above.

By Definition 2, if the adversary wins the game then it did not query  $\mathcal{O}_{VK}$  on either  $B_j$  or  $B_{j'}$ . This in particular means that everything the adversary sees is independent of  $B_j$ 's and  $B_{j'}$ 's secret key bits. Thus, if it is the case that  $\Pi_{\text{OWF}}.F(x_i) \in \{v_i.y_0, v_i.y_1\}$ , with probability at least  $\frac{1}{2}$ ,  $\Pi_{\text{OWF}}.F(x_i) = v_i.y_{\bar{b}}$ , where  $\bar{b} := 1 - b$  and  $b$  is the bit in  $B_j$ 's secret key. Otherwise, if  $\Pi_{\text{OWF}}.F(x_{i'}) \in \{v_{i'}.y_0, v_{i'}.y_1\}$ , with probability at least  $\frac{1}{2}$ ,  $\Pi_{\text{OWF}}.F(x_{i'}) = v_{i'}.y_{\bar{b}}$ , where  $\bar{b} := 1 - b$  but this time  $b$  being the bit in  $B_{j'}$ 's secret key. It is easy to see that one can then reduce winning game  $\mathbf{G}^4$  to breaking the security of the underlying  $\Pi_{\text{OWF}}$  by decrypting the ciphertext  $c_{\text{pp}}$  of signature  $\sigma$ . For each verifier  $B_l$ , and letting  $b$  be the bit in  $B_l$ 's secret key, the  $y_{\bar{b}}$  image in  $B_l$ 's public key is now obtained via a query  $\Pi_{\text{OWF}}\text{-}\mathcal{O}_Y$ . Given  $n_V \leq n_{\text{OWF}}$ , it follows from Equation B.5 that no adversary  $(\varepsilon_{\text{OWF}}, t_{\text{OWF}})$ -breaks the  $(n_{\text{OWF}})$ -security of  $\Pi_{\text{OWF}}$ , implying  $\Pr[\mathbf{AG}^4 = \text{win}] \leq 2 \cdot \varepsilon_{\text{OWF}}$ .  $\square$

### B.2.3 Proof of Unforgeability

**Theorem 5.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E\text{PKE}}) \text{-secure,} \end{aligned} \tag{B.6}$$

with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is

$$\begin{aligned} & (\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P\text{NIZK}}, q_{V\text{NIZK}}) \text{-secure,} \end{aligned} \tag{B.7}$$

and  $\Pi_{\text{OWF}}$  is

$$(\varepsilon_{\text{OWF}}, t_{\text{OWF}}, n_{\text{OWF}}) \text{-secure,} \tag{B.8}$$

with  $t_{\text{OWF}} \gtrsim n_{\text{OWF}} \cdot (t_S + t_F)$  (where  $t_S$  and  $t_F$  are, respectively, the times to run  $\Pi_{\text{OWF}.S}$  and  $\Pi_{\text{OWF}.F}$ ) and with  $n_{\text{OWF}} \geq 1$ , then no adversary  $\mathbf{A}(\varepsilon, t)$ -breaks  $\Pi$ 's

$$\begin{aligned} & (n_S := \max(n_{\text{OWF}} - n_V, 0), n_V := \min(n_{\text{PKE}}, \max(n_{\text{OWF}} - n_S, 0)), \\ & q_S := \min(q_{P\text{NIZK}}, q_{E\text{PKE}}), q_V := q_{V\text{NIZK}}) \text{-Unforgeability,} \end{aligned}$$

with  $\varepsilon > (3 \cdot \varepsilon_{\text{PKE-Corr}} + \varepsilon_{\text{PKE-IND-CPA}}) + \varepsilon_{\text{NIZK-ZK}} + \varepsilon_{\text{NIZK-SS}} + 4 \cdot \varepsilon_{\text{OWF}}$ , with  $t_{\text{PKE}}, t_{\text{OWF}} \approx t + t_{\text{Unforg}} + q_S \cdot t_{S_P} + t_{S_G}$  and with  $t_{\text{NIZK}} \approx t + t_{\text{Unforg}}$ , where  $t_{\text{Unforg}}$  is the time to run  $\Pi$ 's  $\mathbf{G}^{\text{Unforg}}$  game and  $t_{S_P}$  and  $t_{S_G}$  are, respectively, the runtime of  $\Pi_{\text{NIZK}.S_P}$  and  $\Pi_{\text{NIZK}.S_G}$ .

*Proof.* We proceed via a sequence of games [4, 23].

$\mathbf{G}^{\text{Unforg}} \rightsquigarrow \mathbf{G}^1$ :  $\mathbf{G}^1$  is just like  $\mathbf{G}^{\text{Unforg}}$  except that in  $\mathbf{G}^1$  the  $\Pi_{\text{PKE}}$  key pair  $(\text{pk}_0, \text{sk}_0)$  sampled for each party  $B_j$  is assumed to be a correct one.

Note that one can reduce distinguishing these two games to breaking  $\Pi_{\text{PKE}}$ 's correctness: since the reduction holds all secret keys it can handle any oracle queries. Furthermore, given an adversary  $\mathbf{A}$  can only query for the verifier public keys of at most  $n_V \leq n_{\text{PKE}}$  parties and given the reduction only has to rely on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{SK}$  oracle to generate at most one key-pair per party—namely,  $(\text{pk}_0, \text{sk}_0)$ —it follows from Equation B.6 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the  $(n_{\text{PKE}})$ -Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{A}\mathbf{G}^1 = \text{win}] - \Pr[\mathbf{A}\mathbf{G}^{\text{Unforg}} = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^1 \rightsquigarrow \mathbf{G}^2$ : This game hop is just like the previous one (i.e.  $\mathbf{G}^{\text{Unforg}} \rightsquigarrow \mathbf{G}^1$ ), the only difference being that the key-pair which is assumed to be a correct one is now  $(\text{pk}_1, \text{sk}_1)$ . Hence,

$$\left| \Pr[\mathbf{A}\mathbf{G}^2 = \text{win}] - \Pr[\mathbf{A}\mathbf{G}^1 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ : This step is similar to the previous ones, except that this time the key pair that is assumed to be a correct one is the public parameters' public key and the corresponding secret key (i.e. the key pair sampled by  $\Pi.S$ ).

Once again one can reduce distinguishing these games to breaking  $\Pi_{\text{PKE}}$ 's correctness: the reduction has all secret keys so it can handle any oracle queries. In contrast to the reductions for the previous steps, however, this time the reduction only has to rely on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  oracle to generate a single key-pair. Since  $n_{\text{PKE}} \geq 1$ , it then follows from Equation B.6 that no adversary ( $\varepsilon_{\text{PKE-Corr}}$ )-breaks the (1)-Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^3 = \text{win}] - \Pr[\mathbf{AG}^2 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^3 \rightsquigarrow \mathbf{G}^4$ : Game  $\mathbf{G}^4$  is just like  $\mathbf{G}^3$  except that in  $\mathbf{G}^4$  both the  $\text{crs}$  and the NIZK proofs in the signatures output by  $\mathcal{O}_S$  are simulated (i.e. the  $\text{crs}$  is now generated by  $\Pi_{\text{NIZK}}.S_G$  and the NIZK proofs are now generated by  $\Pi_{\text{NIZK}}.S_P$ ).

It is easy to see that one can reduce distinguishing these two games to breaking  $\Pi_{\text{NIZK}}$ 's Zero-Knowledge property, as the reduction holds all secret keys and thus can handle any oracle queries. (Although the reduction does not have the trapdoor for the  $\text{crs}$ , in case the  $\text{crs}$  is a simulated one, since it only has to prove true statements it can rely on oracle  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  for generating the necessary NIZK proofs.) Noting the reduction only has to generate at most one NIZK proof for each  $\mathcal{O}_S$  query, since  $q_S \leq q_{P_{\text{NIZK}}}$  it follows from Equation B.7 that no adversary ( $\varepsilon_{\text{NIZK-ZK}}, t_{\text{NIZK}}$ )-breaks  $\Pi_{\text{NIZK}}$ 's ( $q_{P_{\text{NIZK}}}$ )-ZK security, implying

$$\left| \Pr[\mathbf{AG}^4 = \text{win}] - \Pr[\mathbf{AG}^3 = \text{win}] \right| \leq \varepsilon_{\text{NIZK-ZK}}.$$

$\mathbf{G}^4 \rightsquigarrow \mathbf{G}^5$ : The only difference between games  $\mathbf{G}^4$  and  $\mathbf{G}^5$  is that in game  $\mathbf{G}^5$  ciphertext  $c_{\text{pp}}$  is an encryption of  $m$  followed by a 0-bitstring of appropriate length.

As before the reduction holds all secret keys and thus it can handle any oracle queries (note that the secret key corresponding to the public parameters' public key is never used by the scheme). Note that the reduction only relies on the  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  oracle to generate one key-pair and only queries  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_E$  at most once for each  $\mathcal{O}_S$  query. Hence, as  $n_{\text{PKE}} \geq 1$  and  $q_S \leq q_{E_{\text{PKE}}}$ , it follows from Equation B.6 that no adversary ( $\varepsilon_{\text{PKE-IND-CPA}}, t_{\text{PKE}}$ )-breaks the ( $n_{\text{PKE}}, q_{E_{\text{PKE}}}$ )-IND-CPA security of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^5 = \text{win}] - \Pr[\mathbf{AG}^4 = \text{win}] \right| \leq \varepsilon_{\text{PKE-IND-CPA}}.$$

$\mathbf{G}^5 \rightsquigarrow \mathbf{G}^6$ : Game  $\mathbf{G}^6$  is just like  $\mathbf{G}^5$  except that now it is assumed that the OWF image  $y_0$  in each party's public key is unique. From Lemma 1 and Equation B.8 it then follows

$$\left| \Pr[\mathbf{AG}^6 = \text{win}] - \Pr[\mathbf{AG}^5 = \text{win}] \right| \leq 2 \cdot \varepsilon_{\text{OWF}}.$$

$\mathbf{G}^6 \rightsquigarrow \mathbf{G}^7$ : Game  $\mathbf{G}^7$  is just like game  $\mathbf{G}^6$  except that in  $\mathbf{G}^7$ , for each query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$ , if the NIZK proof  $p$  verifies as valid and was not output by a query  $\mathcal{O}_S(A_i, \vec{V}, m)$  it is assumed that  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ .

One can reduce distinguishing  $\mathbf{G}^6$  and  $\mathbf{G}^7$  to breaking the simulation soundness of  $\Pi_{\text{NIZK}}$ . On one hand, since the reduction holds all secret keys, it can handle any query to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$  and  $\mathcal{O}_V$ . Regarding queries to  $\mathcal{O}_S$ , the reduction can rely on the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  oracle to generate a simulated NIZK proof (even though the NIZK proof is for a false statement, see Definition 23). On the other hand, each query to  $\mathcal{O}_V$  is handled by using the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  oracle to verify the validity of NIZK proof  $p$ . We now argue that if there is a query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  such that the NIZK proof  $p$  of  $\sigma$  verifies as valid for statement  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ , then either indeed  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ , or  $\sigma$  was output by a query  $\mathcal{O}_S(A_i', \vec{V}', m')$  with  $(A_i', \vec{V}', m') = (A_i, \vec{V}, m)$ : if NIZK proof  $p$  in  $\sigma$  was not output by  $\mathcal{O}_S$  as part of a signature, then either  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$  or the reduction would win the simulation soundness game of the underlying  $\Pi_{\text{NIZK}}$ ; if  $p$  was output as part of a signature  $\sigma' = (p, \vec{c}', c_{\text{pp}'})$  by some query  $\mathcal{O}_S(A_i', \vec{V}', m')$  such that  $(A_i', \vec{V}', m', \vec{c}', c_{\text{pp}'}) \neq (A_i, \vec{V}, m, \vec{c}, c_{\text{pp}})$  then  $p$  was not generated for the same NIZK statement—in particular, note that we are assuming all parties have a distinct OWF image  $y_0$  in their public key—implying that either  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$  or once again the reduction would win the simulation soundness game of the underlying  $\Pi_{\text{NIZK}}$ ; it is easy to see it only remains the case where some query  $\mathcal{O}_S(A_i', \vec{V}', m')$  with  $(A_i', \vec{V}', m') = (A_i, \vec{V}, m)$  output signature  $\sigma$ . Note that the reduction generates at most one proof for each  $\mathcal{O}_S$  query and verifies one NIZK proof for each  $\mathcal{O}_V$  query. Because  $q_S \leq q_{P_{\text{NIZK}}}$  and  $q_V \leq q_{V_{\text{NIZK}}}$ , it follows from Equation B.7 that no adversary  $(\varepsilon_{\text{NIZK-SS}}, t_{\text{NIZK}})$ -breaks the  $(q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})$ -Simulation Soundness of  $\Pi_{\text{NIZK}}$ , and so

$$\left| \Pr[\mathbf{AG}^7 = \text{win}] - \Pr[\mathbf{AG}^6 = \text{win}] \right| \leq \varepsilon_{\text{NIZK-SS}}.$$

To conclude we now prove the following claim:

*Claim.*  $\Pr[\mathbf{AG}^7 = \text{win}] \leq 2 \cdot \varepsilon_{\text{OWF}}$ .

*Proof.* Recall that an adversary  $\mathbf{A}$  can only win game  $\mathbf{G}^7$  if it makes a query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  that outputs 1, and  $\mathbf{A}$  did not make any query  $\mathcal{O}_S(A_i, \vec{V}, m)$ ,  $\mathcal{O}_{SK}(A_i)$  nor any query  $\mathcal{O}_{VK}(B_j)$  for  $B_j \in \vec{V}$ . This implies that an adversary can only win  $\mathbf{G}^7$  if it forges a signature  $\sigma$  such that  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  outputs 1 and it did not query  $\mathcal{O}_S$  on  $(A_i, \vec{V}, m)$ . In other words, for every query  $\mathcal{O}_S(A_i', \vec{V}', m')$ , we have  $(A_i, \vec{V}, m) \neq (A_i', \vec{V}', m')$ . Note that all parties are assumed to have distinct public keys—since, as mentioned above, the OWF image  $y_0$  in each party's public key is unique—and so for the adversary to win the game, the NIZK proof  $p$  in  $\sigma$  will have to verify as being valid with respect to a NIZK statement that was never proven by

the  $\mathcal{O}_S$  oracle. From the simulation soundness of  $\Pi_{\text{NIZK}}$  it then follows that  $(\text{pp.pk}, \text{spk}_i, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ , where  $\text{spk}_i$  is  $A_i$ 's signer public key and  $\vec{v}$  is the vector of verifier public keys corresponding to vector of parties  $\vec{V}$ . Taking this one step further, note that  $\mathcal{O}_V$  only outputs 1 if, in addition to the NIZK proof  $p$  being valid, for the least  $i \in \{1, \dots, |\vec{V}|\}$  such that  $V_i = B_j$ ,  $c_{i,b}$  is an encryption of 1 (by correctness, where  $b$  is the bit in  $B_j$ 's secret key). Since by definition  $R_{\text{MDVS}^{\text{adap}}} \subseteq R_{\text{MDVS}^{\text{adap}}\text{-Match}} \cap R_{\text{MDVS}^{\text{adap}}\text{-Unforg}}$ , this implies  $c_{\text{pp}}$  is an encryption of a plaintext  $(m', b', ((b'_1, x'_1), \dots, (b'_l, x'_l)))$  with  $x'_i$  being such that

$$\Pi_{\text{OWF}}.F(x'_i) \in \{\text{spk}.y_0, \text{spk}.y_1, v_i.y_0, v_i.y_1\}.$$

The correctness of  $\text{pp.pk}$  further implies that decrypting  $c_{\text{pp}}$  results in this plaintext. By Definition 3, since the query is a winning one, the adversary could not have queried  $\mathcal{O}_{SK}$  on  $A_i$  nor  $\mathcal{O}_{VK}$  on  $B_j$ . This implies that everything the adversary sees is now completely independent of  $A_i$ 's bit  $b$  in its secret key and  $B_j$ 's bit  $b$  in its secret key; thus, the probability that either  $\Pi_{\text{OWF}}.F(x'_i) = \text{spk}.y_{\bar{b}}$ —with  $\bar{b} := 1 - b$ ,  $b$  being the secret key in  $A_i$ 's secret key—or  $\Pi_{\text{OWF}}.F(x'_i) = v_i.y_{\bar{b}}$ —with  $\bar{b}$  this time being the complement of the bit in the secret key in  $B_j$ —is  $\frac{1}{2}$ . Given the correctness of  $\text{pp.pk}$ , one can then reduce winning  $\mathbf{G}^7$  to breaking the security of the underlying  $\Pi_{\text{OWF}}$ . For each signer and each verifier, letting  $b$  be the bit in the party's secret key, the  $y_{\bar{b}}$  image in the party's public key is now obtained via a query  $\Pi_{\text{OWF}}\text{-}\mathcal{O}_Y$ . Given  $n_S \leq \max(n_{\text{OWF}} - n_V, 0)$  and  $n_V \leq \max(n_{\text{OWF}} - n_S, 0)$ , it follows by Equation B.8 that no adversary  $(\varepsilon_{\text{OWF}}, t_{\text{OWF}})$ -breaks the  $(n_{\text{OWF}})$ -security of  $\Pi_{\text{OWF}}$ , implying  $\Pr[\mathbf{AG}^7 = \text{win}] \leq 2 \cdot \varepsilon_{\text{OWF}}$ .  $\square$

#### B.2.4 Proof of Off-The-Record Security

**Theorem 6.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} &(\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E\text{PKE}})\text{-secure}, \end{aligned} \tag{B.9}$$

with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is

$$\begin{aligned} &(\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P\text{NIZK}}, q_{V\text{NIZK}})\text{-secure}, \end{aligned} \tag{B.10}$$

and  $\Pi_{\text{OWF}}$  is

$$(\varepsilon_{\text{OWF}}, t_{\text{OWF}}, n_{\text{OWF}})\text{-secure}, \tag{B.11}$$

with  $t_{\text{OWF}} \gtrsim n_{\text{OWF}} \cdot (t_S + t_F)$  (where  $t_S$  and  $t_F$  are, respectively, the times to run  $\Pi_{\text{OWF}}.S$  and  $\Pi_{\text{OWF}}.F$ ) and with  $n_{\text{OWF}} \geq 1$ , then no adversary  $\mathbf{A}(\varepsilon, t)$ -breaks  $\Pi$ 's

$$\begin{aligned} &(n_V := n_{\text{PKE}}, q_S := \min(q_{E\text{PKE}}, q_{P\text{NIZK}}), \\ & q_V := q_{V\text{NIZK}}, d_V := q_{E\text{PKE}})\text{-Off-The-Record security}, \end{aligned}$$

with  $\varepsilon > 6 \cdot (\varepsilon_{\text{PKE-Corr}} + \varepsilon_{\text{PKE-IND-CPA}}) + 2 \cdot (\varepsilon_{\text{NIZK-ZK}} + \varepsilon_{\text{NIZK-SS}}) + 4 \cdot \varepsilon_{\text{OWF}}$ , with  $t_{\text{PKE}} \approx t + t_{\text{OTR}} + q_S \cdot t_{S_P} + t_{S_G}$ , and with  $t_{\text{NIZK}} \approx t + t_{\text{OTR}}$ , where  $t_{\text{OTR}}$  is the time to run  $\Pi$ 's  $\mathbf{G}_\beta^{\text{OTR}}$  game experiment (with  $\beta \in \{0, 1\}$ ), and  $t_{S_P}$  and  $t_{S_G}$  are, respectively, the runtime of  $S_P$  and  $S_G$ .

The proof of Theorem 6 relies on an alternative signature verification procedure that is defined in Algorithm 7.

---

**Algorithm 7** Alternative signature verification algorithm for the OTR security reductions. Below,  $\mathbf{sk}_{\text{pp}}$  is the secret key corresponding to the public parameter's public key  $\text{pp.pk}$ .

---

```

Vfypp(spk, vpk, skpp,  $\vec{v}$ ,  $m$ ,  $\sigma := (p, \vec{c}, c_{\text{pp}})$ )
  if  $\Pi_{\text{NIZK}}.V_{\text{crs}}((\text{pp.pk}, \mathbf{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDV}_{\text{S}}\text{adap}}, p) = 1$  then
    ( $m'$ ,  $b'$ ,  $((b'_1, x'_1), \dots, (b'_l, x'_l))$ )  $\leftarrow \Pi_{\text{PKE}}.D_{\text{skpp}}(c_{\text{pp}})$ 
    for  $i = 1, \dots, l$  do
      if  $\text{vpk} = v_i$  then
        return  $b'_i$ 
  return 0

```

---

*Proof.* As before, we proceed in a sequence of games.

For any given adversary  $\mathbf{A}$ , we bound  $\mathbf{A}$ 's advantage

$$\text{Adv}^{\text{OTR}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{\text{OTR}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{OTR}} = \text{win}] - 1 \right|,$$

by bounding, for  $\beta \in \{0, 1\}$ , the difference between the probability of  $\mathbf{A}$  winning  $\mathbf{G}_\beta^{\text{OTR}}$  and winning  $\mathbf{G}_\beta^1$ , and, for  $i \in \{1, \dots, 10\}$ , the difference between the probability of  $\mathbf{A}$  winning  $\mathbf{G}_\beta^i$  and winning  $\mathbf{G}_\beta^{i+1}$ . In other words, for  $\beta \in \{0, 1\}$ , we bound

$$\left| \Pr[\mathbf{AG}_\beta^{\text{OTR}} = \text{win}] - \Pr[\mathbf{AG}_\beta^1 = \text{win}] \right|,$$

and bound, for  $i \in \{1, \dots, 10\}$ ,

$$\left| \Pr[\mathbf{AG}_\beta^i = \text{win}] - \Pr[\mathbf{AG}_\beta^{i+1} = \text{win}] \right|.$$

As we will see, games  $\mathbf{G}_0^{11}$  and  $\mathbf{G}_1^{11}$  are perfectly indistinguishable; it follows

$$\left| \Pr[\mathbf{AG}_0^{11} = \text{win}] + \Pr[\mathbf{AG}_1^{11} = \text{win}] - 1 \right| = 0,$$

implying

$$\begin{aligned}
Adv^{\text{OTR}}(\mathbf{A}) &:= \left| \Pr[\mathbf{AG}_0^{\text{OTR}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{OTR}} = \text{win}] - 1 \right| \\
&\leq \left| \Pr[\mathbf{AG}_0^{\text{OTR}} = \text{win}] - \Pr[\mathbf{AG}_0^1 = \text{win}] \right| \\
&\quad + \sum_{i=1, \dots, 10} \left| \Pr[\mathbf{AG}_0^i = \text{win}] - \Pr[\mathbf{AG}_0^{i+1} = \text{win}] \right| \\
&\quad + \sum_{i=1, \dots, 10} \left| \Pr[\mathbf{AG}_1^i = \text{win}] - \Pr[\mathbf{AG}_1^{i+1} = \text{win}] \right| \\
&\quad + \left| \Pr[\mathbf{AG}_1^{\text{OTR}} = \text{win}] - \Pr[\mathbf{AG}_1^1 = \text{win}] \right|.
\end{aligned}$$

For  $\beta \in \{0, 1\}$ , game hops  $\mathbf{G}_\beta^{\text{OTR}} \rightsquigarrow \mathbf{G}_\beta^1$ ,  $\mathbf{G}_\beta^1 \rightsquigarrow \mathbf{G}_\beta^2$ ,  $\mathbf{G}_\beta^2 \rightsquigarrow \mathbf{G}_\beta^3$ ,  $\mathbf{G}_\beta^3 \rightsquigarrow \mathbf{G}_\beta^4$ ,  $\mathbf{G}_\beta^4 \rightsquigarrow \mathbf{G}_\beta^5$  and  $\mathbf{G}_\beta^5 \rightsquigarrow \mathbf{G}_\beta^6$  are analogous to the ones given in the proof of Theorem 5 (see Section B.2.3), the only difference being that OTR game systems now give the adversary access to the  $\mathcal{O}_{\text{Challenge}}$  oracle instead of giving access to the  $\mathcal{O}_S$  oracle. Nevertheless, it is trivial to adapt the reductions given in the proof of Theorem 5 to this proof. We now proceed with the remaining ones.

$\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ : Game  $\mathbf{G}_\beta^7$  is just like game  $\mathbf{G}_\beta^6$  except that in  $\mathbf{G}_\beta^7$ , for each  $\mathcal{O}_V$  query where NIZK proof  $p$  in the input signature verifies as valid for the corresponding statement, it is assumed that  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}_{\text{adap}}}$ .

One can reduce distinguishing  $\mathbf{G}_\beta^6$  and  $\mathbf{G}_\beta^7$  to breaking the simulation soundness of  $\Pi_{\text{NIZK}}$ . On one hand, since the reduction holds all secret keys, it can handle any query to oracles  $\mathcal{O}_{PP}$ ,  $\mathcal{O}_{SK}$ ,  $\mathcal{O}_{VK}$ ,  $\mathcal{O}_{SPK}$ ,  $\mathcal{O}_{VPK}$  and  $\mathcal{O}_V$ . Regarding queries to  $\mathcal{O}_{\text{Challenge}}$ , the reduction can rely on the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  oracle to generate a simulated NIZK proof (even though the NIZK proof is for a false statement, see Definition 23). On the other hand, each query to  $\mathcal{O}_V$  is handled by using the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  oracle to verify the validity of NIZK proof  $p$ . At this point, it only remains to show that distinguishing  $\mathbf{G}_\beta^6$  and  $\mathbf{G}_\beta^7$  implies the reduction would win the simulation soundness game for the underlying  $\Pi_{\text{NIZK}}$  scheme.

For every query  $\mathcal{O}_V(A_i, B_j, \vec{V}, m, \sigma := (p, \vec{c}, c_{\text{pp}}))$  where  $p$  verifies as a valid NIZK proof (for the corresponding statement), we will assume from now on that signature  $\sigma$  was not output by a query  $\mathcal{O}_{\text{Challenge}}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  (as otherwise by definition the adversary does not win the game). In case  $p$  was not output as part of any signature output by  $\mathcal{O}_{\text{Challenge}}$  then it was not output by the underlying  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  oracle, and so, since it verifies as valid, either indeed  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}_{\text{adap}}}$  or the adversary breaks the simulation soundness of  $\Pi_{\text{NIZK}}$ . In case  $p$  was output as part of a signature  $\sigma' = (p, \vec{c}', c_{\text{pp}}')$  generated by a query  $\mathcal{O}_{\text{Challenge}}(\text{type}, A_i', \vec{V}', m', \mathcal{C})$ , then by assumption we have  $(A_i', \vec{V}', m', \vec{c}', c_{\text{pp}}') \neq (A_i, \vec{V}, m, \vec{c}, c_{\text{pp}})$ . Given all parties have a distinct OWF image  $y_0$  in their public key, it follows that if  $(A_i', \vec{V}') \neq (A_i, \vec{V})$  then either  $\text{spk}_{i'} \neq \text{spk}_i$  or  $\vec{v} \neq \vec{v}'$ . However, in this case the NIZK proof  $p$  verified as

valid for a statement that is different from the one proven by  $\mathcal{O}_{Challenge}$ —and thus also different from any statement proven by the underlying  $\Pi_{NIZK}\text{-}\mathcal{O}_P$  oracle—and thus either  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$  or the adversary breaks the simulation soundness of  $\Pi_{NIZK}$ . If  $(m', \vec{c}', c_{\text{pp}}') \neq (m, \vec{c}, c_{\text{pp}})$  then once again the NIZK proof  $p$  verified as valid for a statement that is different from the one proven by  $\mathcal{O}_{Challenge}$  (and thus either  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$  or the adversary breaks the simulation soundness of  $\Pi_{NIZK}$ ).

To conclude, noting that the reduction only generates at most one NIZK proof for each query to oracle  $\mathcal{O}_{Challenge}$  and verifies at most one NIZK proof for each query to  $\mathcal{O}_V$ , it follows that since  $q_S \leq q_{P_{NIZK}}$  and  $q_V \leq q_{V_{NIZK}}$ , by Equation B.10 no adversary  $(\varepsilon_{NIZK\text{-SS}}, t_{NIZK})$ -breaks  $\Pi_{NIZK}$ 's  $(q_{P_{NIZK}}, q_{V_{NIZK}})$ -Simulation Soundness, implying

$$|\Pr[\mathbf{AG}_\beta^6 = \text{win}] - \Pr[\mathbf{AG}_\beta^7 = \text{win}]| \leq \varepsilon_{NIZK\text{-SS}}.$$

$\mathbf{G}_\beta^7 \rightsquigarrow \mathbf{G}_\beta^8$ : While in game  $\mathbf{G}_\beta^7$  queries to oracle  $\mathcal{O}_V$  are handled by following the normal signature verification procedure, in game  $\mathbf{G}_\beta^8$  these queries are handled by following the alternative signature verification procedure given in Algorithm 7.

Since at this point we are assuming the perfect correctness of all  $\Pi_{PKE}$  key-pairs sampled by the game—which includes the public parameters public key (and corresponding secret key) as well as the two  $\Pi_{PKE}$  pairs sampled for each party—and furthermore are assuming that if a NIZK proof  $p$  verifies as valid for a statement  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}})$  then it must indeed be the case that  $(\text{pp.pk}, \text{spk}, \vec{v}, m, \vec{c}, c_{\text{pp}}) \in L_{\text{MDVS}^{\text{adap}}}$ , it follows that  $\mathbf{G}_\beta^7$  and  $\mathbf{G}_\beta^8$  are perfectly indistinguishable:

$$|\Pr[\mathbf{AG}_\beta^7 = \text{win}] - \Pr[\mathbf{AG}_\beta^8 = \text{win}]| = 0.$$

$\mathbf{G}_\beta^8 \rightsquigarrow \mathbf{G}_\beta^9$ : The only difference between games  $\mathbf{G}_\beta^8$  and  $\mathbf{G}_\beta^9$  is that in  $\mathbf{G}_\beta^9$  each signature  $\sigma := (p, \vec{c}, c_{\text{pp}})$  output by a query  $\mathcal{O}_{Challenge}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  is such that for all  $i \in \{1, \dots, |\vec{V}|\}$ , ciphertext  $c_{i, \bar{b}}$  in the vector of ciphertexts  $\vec{c}$ —where  $\bar{b} := 1 - b$ ,  $b$  being the secret bit of party  $V_i$ —is an encryption of bit 0.

Once again, one can reduce distinguishing the two games to breaking the IND-CPA security of the underlying scheme  $\Pi_{PKE}$ : since the reduction holds exactly the same secret information as it did in the last game, it can handle all queries as before. Furthermore, as for each verifier the reduction only has to rely on  $\Pi_{PKE}\text{-}\mathcal{O}_{PK}$  to generate one public key and for each query  $\mathcal{O}_{Challenge}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  the reduction queries  $\Pi_{PKE}\text{-}\mathcal{O}_E$  at most  $|\vec{V}|$  times, given  $n_V \leq n_{PKE}$  and  $d_V \leq q_{E_{PKE}}$ , it follows by Equation B.9 that no adversary  $(\varepsilon_{PKE\text{-IND-CPA}}, t_{PKE})$ -breaks  $\Pi_{PKE}$ 's  $(n_{PKE}, q_{E_{PKE}})$ -IND-CPA security, implying

$$|\Pr[\mathbf{AG}_\beta^8 = \text{win}] - \Pr[\mathbf{AG}_\beta^9 = \text{win}]| \leq \varepsilon_{PKE\text{-IND-CPA}}.$$

$\mathbf{G}_\beta^9 \rightsquigarrow \mathbf{G}_\beta^{10}$ : The difference between games  $\mathbf{G}_\beta^9$  and  $\mathbf{G}_\beta^{10}$  is that in  $\mathbf{G}_\beta^{10}$  each signature  $\sigma := (p, \vec{c}, c_{\text{pp}})$  output by a query  $\mathcal{O}_{\text{Challenge}}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  is such that for all  $i \in \{1, \dots, |\vec{V}|\}$ , ciphertext  $c_{i, \bar{b}}$  in the vector of ciphertexts  $\vec{c}$  returns to being an encryption of the same bit as it was in  $\mathbf{G}_\beta^9$ , whereas  $c_{i, b}$  becomes an encryption of bit 0.

Note that for any party  $B_j$  the existence of a query  $\mathcal{O}_{\text{Challenge}}(\text{type}, A_i, \vec{V}, m, \mathcal{C})$  with  $B_j \in \vec{V}$  implies there is no query to  $\mathcal{O}_{VK}$  on  $B_j$  (and vice-versa). Thus all the adversary sees is independent of  $B_j$ 's secret key bit. It then follows that  $\mathbf{G}_\beta^9$  is perfectly indistinguishable from  $\mathbf{G}_\beta^{10}$ , and hence

$$|\Pr[\mathbf{AG}_\beta^9 = \text{win}] - \Pr[\mathbf{AG}_\beta^{10} = \text{win}]| = 0.$$

$\mathbf{G}_\beta^{10} \rightsquigarrow \mathbf{G}_\beta^{11}$ : This step is analogous to step  $\mathbf{G}_\beta^8 \rightsquigarrow \mathbf{G}_\beta^9$ , except that this time  $c_{i, b}$  is an encryption of bit 0. It follows

$$\left| \Pr[\mathbf{AG}_\beta^8 = \text{win}] - \Pr[\mathbf{AG}_\beta^9 = \text{win}] \right| \leq \varepsilon_{\text{PKE-IND-CPA}}.$$

To conclude the proof, note that  $\mathbf{G}_0^{11}$  is perfectly indistinguishable from  $\mathbf{G}_1^{11}$ , as everything an adversary sees when interacting with either game is exactly the same (independently of which game the adversary is actually interacting with). Also, note that each intermediate game simply has to emulate the original game towards  $\mathbf{A}$ —with a few tweaks that, apart from the generation of a simulated  $\text{crs}$  and the generation of simulated NIZK proofs, do not affect the time for emulating the game. Letting  $t_{\text{OTR}}$  be the time to run  $\Pi$ 's  $\mathbf{G}_\beta^{\text{OTR}}$  game experiment (with  $\beta \in \{0, 1\}$ ),  $t_{S_P}$  be the runtime of  $S_P$  and  $t_{S_G}$  be the runtime of  $S_G$ , it follows

$$\begin{aligned} t_{\text{PKE}} &\approx t + t_{\text{OTR}} + q_S \cdot t_{S_P} + t_{S_G}, \\ t_{\text{NIZK}} &\approx t + t_{\text{OTR}}. \end{aligned}$$

□

### B.3 PKEBC Construction Security Proofs

In this section we give the formal security theorems and corresponding full proofs for the PKEBC construction given in Section 5.4.

#### B.3.1 Proof of Correctness

**Theorem 7.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} &(\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ &t_{\text{PKE}}, n_{\text{PKE}}, q_{E_{\text{PKE}}}, \text{Corr})\text{-secure,} \end{aligned} \tag{B.12}$$

with  $t_{\text{PKE}} \gtrsim n_{\text{PKE}} \cdot t_G + t_D$  (where  $t_G$  and  $t_D$  are, respectively, the times to run  $\Pi_{\text{PKE}.G}$  and  $\Pi_{\text{PKE}.D}$ ) and with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is

$$\begin{aligned} & (\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})\text{-secure}, \end{aligned} \quad (\text{B.13})$$

and  $\Pi_{\text{SKE}}$  is

$$(\varepsilon_{\text{SKE-1-IND-CPA}}, t_{\text{SKE}}, q_{E_{\text{SKE}}}, \text{Corr})\text{-secure}, \quad (\text{B.14})$$

then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's

$$(n := n_{\text{PKE}}, q_E := q_{P_{\text{NIZK}}}, q_D := q_{V_{\text{NIZK}}})\text{-Correctness},$$

with  $\varepsilon > \varepsilon_{\text{NIZK-Complete}} + 2 \cdot \varepsilon_{\text{PKE-IND-CPA}} + 3 \cdot \varepsilon_{\text{PKE-Corr}}$ , with  $t_{\text{NIZK}} \approx t + t_{\text{Corr}}$ —where  $t_{\text{Corr}}$  is the time to run  $\Pi$ 's  $\mathbf{G}^{\text{Corr}}$  game—and with  $t < t_{\text{PKE}}$ .

*Proof.* We proceed in a sequence of games.

$\mathbf{G}^{\text{Corr}} \rightsquigarrow \mathbf{G}^1$ : Game  $\mathbf{G}^1$  is just like the original game  $\mathbf{G}^{\text{Corr}}$ , except that in  $\mathbf{G}^1$  for each ciphertext  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  output by a query  $\mathcal{O}_E(\vec{V}, m)$ , if  $\mathcal{O}_D$  is queried on input  $(B_j, c)$  it no longer verifies  $p$ 's validity and simply proceeds as if  $p$  would verify as being valid.

Games  $\mathbf{G}^{\text{Corr}}$  and  $\mathbf{G}^1$  are perfectly indistinguishable unless there is a query  $\mathcal{O}_D(B_j, c)$  where  $c$  was output by some query  $\mathcal{O}_E(\vec{V}, m)$  such that  $B_j \in \vec{V}$ , and the verification of the NIZK proof  $p$  in  $c$  fails. One can then reduce distinguishing these games to breaking  $\Pi_{\text{NIZK}}$ 's completeness: the reduction holds the secret keys of every party, and so it can trivially handle any oracle queries. Noting the reduction makes at most one  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  query for each  $\mathcal{O}_S$  query and at most one  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  query for each  $\mathcal{O}_V$  query, as  $\mathbf{A}$  only makes up to  $q_E \leq q_{P_{\text{NIZK}}}$  queries to  $\mathcal{O}_E$  and  $q_D \leq q_{V_{\text{NIZK}}}$  queries to  $\mathcal{O}_D$ , it follows from Equation B.13, that no adversary  $(\varepsilon_{\text{NIZK-Complete}}, t_{\text{NIZK}})$ -breaks the  $(q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})$ -Completeness of  $\Pi_{\text{NIZK}}$ , implying

$$\left| \Pr[\mathbf{AG}^1 = \text{win}] - \Pr[\mathbf{AG}^{\text{Corr}} = \text{win}] \right| \leq \varepsilon_{\text{NIZK-Complete}}.$$

$\mathbf{G}^1 \rightsquigarrow \mathbf{G}^2$ :  $\mathbf{G}^2$  is just like  $\mathbf{G}^1$ , except that now there are no two parties with the same public key. It follows from Lemma 2 and Equation B.12 that

$$\left| \Pr[\mathbf{AG}^2 = \text{win}] - \Pr[\mathbf{AG}^1 = \text{win}] \right| \leq 2 \cdot \varepsilon_{\text{PKE-IND-CPA}} + \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ :  $\mathbf{G}^3$  is just like  $\mathbf{G}^2$ , except that now  $\mathcal{O}_D$  behaves differently. For each query  $(B_j, c)$  to  $\mathcal{O}_D$ , where  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  is the output of a query  $\mathcal{O}_E(\vec{V}, m)$ ,  $\mathcal{O}_D$  now skips decryption attempts for every index  $i \in \{1, \dots, |\vec{V}|\}$  such that  $V_i \neq B_j$ .

Games  $\mathbf{G}^3$  and  $\mathbf{G}^2$  are perfectly indistinguishable unless there is a decryption query  $\mathcal{O}_D(B_j, c)$  where  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  was the output of a query  $\mathcal{O}_E(\vec{V}, m)$  and for some  $i \in \{1, \dots, |\vec{c}|\}$ , ciphertext  $c_{i,0} \in \vec{c}$  is an encryption of two different values under  $\text{pp.pk}$ —one being  $\text{pk}_j$  and the other being the public key  $\text{pk}_i$  of party  $V_i \in \vec{V}$ . Note that one can reduce distinguishing these two games to breaking  $\Pi_{\text{PKE}}$ 's correctness. More concretely, the reduction only has to rely on the underlying oracle  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{\text{PK}}$  to generate a single public key ( $\text{pp.pk}$ ), but otherwise can handle any oracle queries since it holds all necessary secret keys. Putting things together, since by Equation B.12 no adversary ( $\varepsilon_{\text{PKE-Corr}}$ )-breaks the (1)-Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^3 = \text{win}] - \Pr[\mathbf{AG}^2 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^3 \rightsquigarrow \mathbf{G}^4$ : Game  $\mathbf{G}^4$  is just like  $\mathbf{G}^3$  except that once again  $\mathcal{O}_D$  behaves differently. Again, let  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  be the output of  $\mathcal{O}_E$  when queried on some input  $(\vec{V}, m)$ . If  $\mathcal{O}_D$  is queried on input  $(B_j, c)$  such that  $B_j \in \vec{V}$  and letting  $i \in \{1, \dots, |\vec{V}|\}$  be the least index such that  $V_i = B_j$  and letting  $b$  be the bit in  $B_j$ 's secret key,  $\mathcal{O}_D$  no longer follows the procedure of trying to decrypt  $c_{i,b,1}$ , reconstructing  $c_{i,0}$  and then decrypting  $c_{i,b,2}$  to obtain  $k_{\text{sym}}$ —the  $\Pi_{\text{SKE}}$ 's symmetric key that was generated in the  $\mathcal{O}_E$  query. Instead,  $\mathcal{O}_D$  simply proceeds as if this check (i.e. reconstructing  $c_{i,0}$ ) succeeded for index  $i$ , and  $c_{i,b,2}$ 's decryption resulted in  $k_{\text{sym}}$ .

It is easy to see one can reduce distinguishing these two games to breaking the correctness of the underlying PKE scheme, similarly to the previous game hop (i.e.  $\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ ). The main difference is that now the reduction relies on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{\text{SK}}$  to generate a key-pair for each party: for each party  $B_j$ , the reduction uses  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{\text{SK}}$  to generate key-pair  $(\text{pk}_b, \text{sk}_b)$ , where  $b$  is the bit in  $B_j$ 's secret key. As before, the reduction has access to all the secret keys, and thus it can handle any oracle queries. Since  $\mathbf{A}$  queries on at most  $n \leq n_{\text{PKE}}$  different parties, it follows from Equation B.12 that no adversary ( $\varepsilon_{\text{PKE-Corr}}$ )-breaks the  $(n_{\text{PKE}})$ -Correctness property of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^4 = \text{win}] - \Pr[\mathbf{AG}^3 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^4 \rightsquigarrow \mathbf{G}^5$ :  $\mathbf{G}^5$  is just like  $\mathbf{G}^4$  except that again  $\mathcal{O}_D$  behaves differently. Let  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  be the output of  $\mathcal{O}_E$  when queried on some input  $(\vec{V}, m)$ . If  $\mathcal{O}_D$  is queried on input  $(B_j, c)$  such that  $B_j \in \vec{V}$  and letting  $i \in \{1, \dots, |\vec{V}|\}$  be the least index such that  $V_i = B_j$ ,  $\mathcal{O}_D$  no longer tries decrypting  $c_{\text{sym}}$  using  $k_{\text{sym}}$ , and instead simply proceeds as if the decryption had output the  $(\vec{v}, m)$  pair that was encrypted by the  $\mathcal{O}_E$  query.

As before, one can reduce distinguishing the two games to winning the correctness game of  $\Pi_{\text{SKE}}$ . It follows from Equation B.14 that  $\Pi_{\text{SKE}}$  is perfectly correct, which implies

$$\left| \Pr[\mathbf{AG}^5 = \text{win}] - \Pr[\mathbf{AG}^4 = \text{win}] \right| = 0.$$

Finally, noting that in  $\mathbf{G}^5$  any query  $\mathcal{O}_D(B_j, c)$ —where  $c$  was output by a query  $\mathcal{O}_E(\vec{V}, m)$  with  $B_j \in \vec{V}$ —must output  $(\vec{v}, m)$ — $\vec{v}$  being the vector of public keys corresponding to the vector of parties  $\vec{V}$ —it follows

$$\Pr[\mathbf{AG}^5 = \text{win}] = 0.$$

□

### B.3.2 Proof of Robustness

**Theorem 8.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E\text{PKE}}) \text{-secure,} \end{aligned} \tag{B.15}$$

with  $t_{\text{PKE}} \gtrsim n_{\text{PKE}} \cdot t_G + t_D$  (where  $t_G$  and  $t_D$  are, respectively, the times to run  $\Pi_{\text{PKE}.G}$  and  $\Pi_{\text{PKE}.D}$ ) and  $n_{\text{PKE}} \geq 1$ , then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's ( $n := n_{E\text{PKE}}$ )-Robustness, with  $\varepsilon > 2 \cdot \varepsilon_{\text{PKE-IND-CPA}} + 2 \cdot \varepsilon_{\text{PKE-Corr}}$  and  $t < t_{\text{PKE}}$ .

*Proof.* This result can be proven by following (some of) the arguments given in the proof of Theorem 7 (see Section B.3.1). More concretely, one would first hop from the original  $\mathbf{G}^{\text{Rob}}$  Robustness game to one where all parties are assumed to have distinct public keys (see  $\mathbf{G}^2$ ), and then to one where decryption queries for ciphertexts not meant for the decrypting party would simply output  $\perp$  (see  $\mathbf{G}^3$  of Section B.3.1). □

### B.3.3 Proof of Consistency

**Theorem 9.** *If  $\Pi_{\text{PKE}}$  is*

$$\begin{aligned} & (\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, \\ & t_{\text{PKE}}, n_{\text{PKE}}, q_{E\text{PKE}}) \text{-secure,} \end{aligned} \tag{B.16}$$

with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is

$$\begin{aligned} & (\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, \\ & t_{\text{NIZK}}, q_{P\text{NIZK}}, q_{V\text{NIZK}}) \text{-secure,} \end{aligned} \tag{B.17}$$

$\Pi_{\text{SKE}}$  is

$$(\varepsilon_{\text{SKE-1-IND-CPA}}, t_{\text{SKE}}, q_{E\text{SKE}}) \text{-secure,} \tag{B.18}$$

and  $\Pi_{\text{NIZK}.V}$  is a deterministic algorithm, then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's

$$(n := n_{\text{PKE}}, q_D := q_{V\text{NIZK}}) \text{-Consistency,}$$

with  $\varepsilon > \varepsilon_{\text{NIZK-Sound}} + 3 \cdot \varepsilon_{\text{PKE-Corr}}$  and with  $t_{\text{NIZK}} \approx t + t_{\text{Cons}}$ , where  $t_{\text{Cons}}$  is the time to run  $\Pi$ 's  $\mathbf{G}^{\text{Cons}}$  game.

*Proof.* We prove this result via game hopping.

$\mathbf{G}^{\text{Cons}} \rightsquigarrow \mathbf{G}^1$ : Game  $\mathbf{G}^1$  is just like the original game  $\mathbf{G}^{\text{Cons}}$ , except that whenever  $\mathcal{O}_D$  is queried on an input  $(B_j, c)$ , with  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  such that  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \notin L_{\text{PKCEBC}^{\text{adap}}}$ , the oracle outputs  $\perp$ .

It is easy to see that  $\mathbf{G}^1$  is perfectly indistinguishable from  $\mathbf{G}^{\text{Cons}}$  unless  $\mathbf{A}$  makes a decryption query on a ciphertext  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  such that the NIZK proof  $p$  verifies as being valid but the statement is not true (i.e.  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \notin L_{\text{PKCEBC}^{\text{adap}}}$ ). One can then reduce distinguishing these two games to breaking the soundness of  $\Pi_{\text{NIZK}}$ , as the reduction holds the secrets of all parties, and thus it can handle any oracle queries. Since the reduction only has to verify the validity of a NIZK proof for each query the adversary makes to  $\mathcal{O}_D$ —which it does using the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  oracle of the underlying security game—and since the adversary can only make up to  $q_D \leq q_{V_{\text{NIZK}}}$  decryption queries, it follows from Equation B.17 that no adversary  $(\varepsilon_{\text{NIZK-Sound}}, t_{\text{NIZK}})$ -breaks the  $(q_{V_{\text{NIZK}}})$ -Soundness of  $\Pi_{\text{NIZK}}$ , implying

$$\left| \Pr[\mathbf{AG}^1 = \text{win}] - \Pr[\mathbf{AG}^{\text{Cons}} = \text{win}] \right| \leq \varepsilon_{\text{NIZK-Sound}}.$$

$\mathbf{G}^1 \rightsquigarrow \mathbf{G}^2$ : The only difference between  $\mathbf{G}^2$  and  $\mathbf{G}^1$  is that in  $\mathbf{G}^2$  the public key of the public parameters  $(\text{pp.pk})$  and the corresponding secret key  $\text{sk}_{\text{pp}}$  are assumed to be correct.

It is easy to see that one can reduce distinguishing the two games to breaking the correctness of  $\Pi_{\text{PKE}}$ : since the reduction holds all secret keys, it can handle any oracle queries. Noting that the reduction only queries the underlying game for the public key of a single party (which it does via the  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  oracle), it follows from Equation B.16 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the (1)-Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^2 = \text{win}] - \Pr[\mathbf{AG}^1 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ : Game  $\mathbf{G}^3$  only differs from  $\mathbf{G}^2$  in that the key pair  $(\text{pk}_0, \text{sk}_0)$  of each party  $B_j$  is assumed to be correct.

Similarly to the previous step, one can reduce distinguishing the two game systems to winning the correctness game of the underlying  $\Pi_{\text{PKE}}$ . Given the reduction queries for at most one key for each party, since  $n \leq n_{\text{PKE}}$  it follows from Equation B.16 that no adversary  $(\varepsilon_{\text{PKE-Corr}})$ -breaks the  $(n_{\text{PKE}})$ -Correctness of  $\Pi_{\text{PKE}}$ , implying

$$\left| \Pr[\mathbf{AG}^3 = \text{win}] - \Pr[\mathbf{AG}^2 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}^3 \rightsquigarrow \mathbf{G}^4$ : This game hop is analogous to the previous one ( $\mathbf{G}^2 \rightsquigarrow \mathbf{G}^3$ ) except that now the key-pairs that are assumed to be correct are each party's  $(\text{pk}_1, \text{sk}_1)$  key-pair.

$\mathbf{G}^4 \rightsquigarrow \mathbf{G}^5$ :  $\mathbf{G}^5$  differs from  $\mathbf{G}^4$  in that in  $\mathbf{G}^5$  it is assumed that  $\Pi_{\text{SKE}}$  is perfectly correct. It then follows from Equation B.18 that

$$\left| \Pr[\mathbf{AG}^5 = \text{win}] - \Pr[\mathbf{AG}^4 = \text{win}] \right| = 0.$$

To conclude this proof it only remains to prove the following claim:

*Claim.* For any adversary  $\mathbf{A}$ ,  $\Pr[\mathbf{AG}^5 = \text{win}] = 0$ .

*Proof.*  $\mathbf{A}$  wins  $\mathbf{G}^5$  if it queries  $\mathcal{O}_D$  on inputs  $(B_i, c)$  and  $(B_j, c)$  for some  $B_i$  and  $B_j$  and some ciphertext  $c$ , and the first query outputs  $(\vec{v}, m) \neq \perp$  with  $\text{pk}_j \in \vec{v}$  (where  $\text{pk}_j$  is  $B_j$ 's public key) whereas the second outputs either  $\perp$  or some  $(\vec{v}', m')$  with  $(\vec{v}', m') \neq (\vec{v}, m)$ . Consider any two queries  $q_{D,i}$  and  $q_{D,j}$  that  $\mathbf{A}$  makes to  $\mathcal{O}_D$  on inputs  $(B_i, c)$  and  $(B_j, c)$ , respectively, such that  $q_{D,i}$  outputs  $(\vec{v}, m)$  with  $(\vec{v}, m) \neq \perp$  and  $\text{pk}_j \in \vec{v}$ . (If  $\mathbf{A}$  does not make any two queries satisfying these conditions, it does not win  $\mathbf{G}^5$ .) In the following, let  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  be the input ciphertext of both  $q_{D,i}$  and  $q_{D,j}$ .

To prove this claim we will first show that since  $q_{D,i}$  outputs a pair  $(\vec{v}, m) \neq \perp$  then  $c_{\text{pp}}$  must be an encryption of  $m$  under  $\text{pp.pk}$ —i.e. for some sequence of random coins  $r_{\text{pp}}$  we have  $c_{\text{pp}} = \Pi_{\text{PKE}}.E(\text{pp.pk}, m; r_{\text{pp}})$ —and for  $l \in \{1, \dots, |\vec{v}|\}$  each ciphertext  $c_{l,0}$  is an encryption of  $v_l$  under  $\text{pp.pk}$ —i.e. for some sequence of random coins  $r_{l,0}$ , we have  $c_{l,0} = \Pi_{\text{PKE}}.E(\text{pp.pk}, v_l; r_{l,0})$ . Then, we will show that if  $q_{D,j}$  outputs some pair  $(\vec{v}', m') \neq \perp$ , then it must be the case that  $(\vec{v}', m') = (\vec{v}, m)$ . Finally, we will show that  $q_{D,j}$  does not output  $\perp$ , implying that it must output the same pair  $(\vec{v}, m)$  that was output by  $q_{D,i}$  (and so the adversary cannot win the game).

First, since query  $q_{D,i}$  does not output  $\perp$ , NIZK proof  $p$  verified as being valid; the soundness of  $\Pi_{\text{NIZK}}$  implies  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$ . By the definition of the decryption algorithm, it follows that for some  $l \in \{1, \dots, |\vec{c}|\}$ , the oracle decrypted  $c_{l,b,1}$  obtaining a sequence of random coins  $r_{l,0}$  such that  $c_{l,0} = \Pi_{\text{PKE}}.E(\text{pp.pk}, \text{pk}_i; r_{l,0})$ . By the correctness of  $\text{pp.pk}$ , there is no sequence of random coins  $r$  such that  $c_{l,0} = \Pi_{\text{PKE}}.E(\text{pp.pk}, \text{pk}'_i; r)$ , for any  $\text{pk}'_i \neq \text{pk}_i$ . Since  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$ , it then follows there are sequences of random coins  $r_{l,b,2}$  and  $r_{\text{sym}}$  such that  $c_{l,b,2} = \Pi_{\text{PKE}}.E(\text{pk}_i, \Pi_{\text{SKE}}.G(1^k, r_{\text{sym}}); r_{l,b,2})$ . In the following, let  $k_{\text{sym}} = \Pi_{\text{SKE}}.G(1^k, r_{\text{sym}})$ . By the correctness of each party's  $(\text{pk}_b, \text{sk}_b)$  key-pair (where  $b$  is the bit in the party's secret key) the decryption of  $c_{l,b,2}$  outputs  $k_{\text{sym}}$ . By the definition of the decryption algorithm, since  $q_{D,i}$  outputs  $(\vec{v}, m)$ , then the decryption of  $c_{\text{sym}}$  resulted in this same pair  $(\vec{v}, m)$ . Again since  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$ , and by the correctness of  $\Pi_{\text{SKE}}$  it follows that there is a sequence of random coins  $r_{\text{sym}}'$  such that  $c_{\text{sym}} = \Pi_{\text{SKE}}.E(k_{\text{sym}}, (\vec{v}, m); r_{\text{sym}}')$ . To conclude the first step of the claim's proof, once again since  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$ ,  $c_{\text{pp}}$  is an encryption of  $m$  under  $\text{pp.pk}$  and for  $k \in \{1, \dots, |\vec{v}|\}$  each ciphertext  $c_{k,0}$  is an encryption of  $v_k$  under  $\text{pp.pk}$ .

Recall that by assumption the output  $(\vec{v}, m)$  of query  $q_{D,i}$  is such that  $\text{pk}_j \in \vec{v}$ . Consider any  $l \in \{1, \dots, |\vec{v}|\}$  with  $v_l = \text{pk}_j$ . Given  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in$

$L_{\text{PKEBC}^{\text{adap}}}$  and letting  $k_{\text{sym}}$  be the same as above, it follows from the correctness of each party's  $(\text{pk}_b, \text{sk}_b)$  key-pair (where  $b$  is the bit in the party's secret key) that if the oracle tries to decrypt  $c_{l,b,2}$  using  $B_j$ 's secret key, the decryption will yield  $k_{\text{sym}}$ . By the correctness of  $\Pi_{\text{SKE}}$  and since  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$ , any decryption of  $c_{\text{sym}}$  under  $k_{\text{sym}}$  results in the same pair  $(\vec{v}, m)$ . Noting that the correctness of  $\text{pp.pk}$  implies that the oracle will not attempt to decrypt any ciphertext  $c_{k,b,2}$  with  $v_k \neq \text{pk}_j$  (where  $k \in \{1, \dots, |\vec{v}|\}$ )—since there is no sequence of coins  $r$  such that  $c_{k,0} = \Pi_{\text{PKE}}.E(\text{pp.pk}, \text{pk}_j; r)$ —it then follows that if  $q_{D,j}$  does not output  $\perp$ , then it outputs the same pair as query  $q_{D,i}$ .

To conclude the proof it only remains to show that query  $q_{D,j}$  does not output  $\perp$ . Since  $\Pi_{\text{NIZK}}$ 's proof verification algorithm  $V$  is deterministic and because query  $q_{D,i}$  does not output  $\perp$ , the NIZK proof  $p$  in ciphertext  $c$  also verifies as being valid in query  $q_{D,j}$ . Furthermore, on one hand, and as argued above, the correctness of  $\text{pp.pk}$  implies the oracle will skip decryption attempts for every index  $k \in \{1, \dots, |\vec{v}|\}$  such that  $\text{pk}_j \neq v_k$ . On the other hand, since  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBC}^{\text{adap}}}$  and due to the correctness of  $B_j$ 's  $(\text{pk}_b, \text{sk}_b)$  key-pair (where  $b$  is the bit in the  $B_j$ 's secret key), for each  $l \in \{1, \dots, |\vec{v}|\}$  such that  $v_l = \text{pk}_j$ , decrypting  $c_{l,b,1}$  would result in a sequence  $r$  such that  $c_{l,0} = \Pi_{\text{PKE}}.E(\text{pp.pk}, \text{pk}_j; r)$ . This means that for the least  $l \in \{1, \dots, |\vec{v}|\}$  such that  $v_l = \text{pk}_j$  the oracle will attempt to decrypt  $c_{l,b,2}$ ; as argued above, this implies that on query  $q_{D,j}$  the oracle will output the same pair  $(\vec{v}, m)$  as it did on query  $q_{D,i}$ , which concludes the proof of this claim.  $\square$

### B.3.4 Proof of (IND + IK)-CCA-2<sup>adap</sup> Security

**Theorem 10.** *If  $\Pi_{\text{PKE}}$  is*

$$(\varepsilon_{\text{PKE-Corr}}, \varepsilon_{\text{PKE-IND-CPA}}, \varepsilon_{\text{PKE-IK-CPA}}, t_{\text{PKE}}, n_{\text{PKE}}, q_{E_{\text{PKE}}})\text{-secure}, \quad (\text{B.19})$$

with  $n_{\text{PKE}} \geq 1$ ,  $\Pi_{\text{NIZK}}$  is

$$(\varepsilon_{\text{NIZK-Complete}}, \varepsilon_{\text{NIZK-Sound}}, \varepsilon_{\text{NIZK-ZK}}, \varepsilon_{\text{NIZK-SS}}, t_{\text{NIZK}}, q_{P_{\text{NIZK}}}, q_{V_{\text{NIZK}}})\text{-secure}, \quad (\text{B.20})$$

and  $\Pi_{\text{SKE}}$  is

$$(\varepsilon_{\text{SKE-1-IND-CPA}}, t_{\text{SKE}}, q_{E_{\text{SKE}}})\text{-secure}, \quad (\text{B.21})$$

then no adversary  $\mathbf{A}$   $(\varepsilon, t)$ -breaks  $\Pi$ 's

$$(n := n_{\text{PKE}} - 2, d_E := q_{E_{\text{PKE}}}, q_E := \min(q_{P_{\text{NIZK}}}, q_{E_{\text{SKE}}}), q_D := q_{V_{\text{NIZK}}})\text{-}(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}} \text{ security},$$

with

$$\begin{aligned}
\varepsilon &> (6 \cdot \varepsilon_{\text{PKE-Corr}} + 12 \cdot \varepsilon_{\text{PKE-IND-CPA}} + 8 \cdot \varepsilon_{\text{PKE-IK-CPA}}) \\
&\quad + 2 \cdot (\varepsilon_{\text{NIZK-ZK}} + \varepsilon_{\text{NIZK-Sound}} + \varepsilon_{\text{NIZK-SS}}) \\
&\quad + 2 \cdot \varepsilon_{\text{SKE-1-IND-CPA}}, \\
t_{\text{PKE}}, t_{\text{SKE}} &\approx t + t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}} + q_E \cdot t_{S_P} + t_{S_G}, \\
t_{\text{NIZK}} &\approx t + t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}},
\end{aligned}$$

where  $t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}$  is the time to run  $\Pi$ 's  $\mathbf{G}_{\beta}^{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}$  game experiment (for any  $\beta \in \{0, 1\}$ ),  $t_{S_P}$  is the runtime of  $S_P$ , and  $t_{S_G}$  is the runtime of  $S_G$  ( $S = (S_G, S_P)$  is the simulator of  $\Pi_{\text{NIZK}}$ ).

The proof of Theorem 10 relies on an alternative decryption procedure that is defined in Algorithm 8.

---

**Algorithm 8** Alternative decryption algorithm for the (IND + IK)-CCA-2 security reductions. Below,  $\mathbf{sk}_{\text{pp}}$  is the secret key corresponding to the public parameter's public key (i.e.  $\text{pp.pk}$ ) and  $\mathbf{pk}$  is the public key of the party who is supposed to decrypt  $c$ .

---

```

 $D_{\text{pp}}(\mathbf{sk}_{\text{pp}}, \mathbf{pk}, c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}}))$ 
  if  $\Pi_{\text{NIZK}}.V_{\text{crs}}((1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \in L_{\text{PKEBCCadap}}, p) = \text{valid}$  then
     $m \leftarrow \Pi_{\text{PKE}}.D_{\text{skpp}}(c_{\text{pp}})$ 
    for  $j = 1, \dots, |\vec{c}|$  do
       $v_j \leftarrow \Pi_{\text{PKE}}.D_{\text{skpp}}(c_{j,0})$ 
     $\vec{v} := (v_1, \dots, v_{|\vec{v}|})$ 
    if  $\mathbf{pk} \in \vec{v}$  then
      return  $(\vec{v}, m)$ 
  return  $\perp$ 

```

---

*Proof.* This proof proceeds in a sequence of game hops.

For simplicity of notation, we will refer to  $\mathbf{G}_{\beta}^{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}$  as  $\mathbf{G}_{\beta}^{\text{CCA}}$ , for  $\beta \in \{0, 1\}$ . For any given adversary  $\mathbf{A}$ , we bound  $\mathbf{A}$ 's advantage

$$Adv^{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) := \left| \Pr[\mathbf{AG}_0^{\text{CCA}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{CCA}} = \text{win}] - 1 \right|,$$

by bounding, for  $\beta \in \{0, 1\}$ , the difference between the probability of  $\mathbf{A}$  winning  $\mathbf{G}_{\beta}^{\text{CCA}}$  and winning  $\mathbf{G}_{\beta}^1$ , and, for  $i \in \{1, \dots, 19\}$ , the difference between the probability of  $\mathbf{A}$  winning  $\mathbf{G}_{\beta}^i$  and winning  $\mathbf{G}_{\beta}^{i+1}$ . In other words, for  $\beta \in \{0, 1\}$ , we bound

$$\left| \Pr[\mathbf{AG}_{\beta}^{\text{CCA}} = \text{win}] - \Pr[\mathbf{AG}_{\beta}^1 = \text{win}] \right|,$$

and bound, for  $i \in \{1, \dots, 19\}$ ,

$$\left| \Pr[\mathbf{AG}_{\beta}^i = \text{win}] - \Pr[\mathbf{AG}_{\beta}^{i+1} = \text{win}] \right|.$$

Since  $\mathbf{G}_0^{20}$  is perfectly indistinguishable from  $\mathbf{G}_1^{20}$ ,

$$\left| \Pr[\mathbf{AG}_0^{20} = \text{win}] + \Pr[\mathbf{AG}_1^{20} = \text{win}] - 1 \right| = 0.$$

This then implies

$$\begin{aligned} Adv^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) &:= \left| \Pr[\mathbf{AG}_0^{\text{CCA}} = \text{win}] + \Pr[\mathbf{AG}_1^{\text{CCA}} = \text{win}] - 1 \right| \\ &\leq \left| \Pr[\mathbf{AG}_0^{\text{CCA}} = \text{win}] - \Pr[\mathbf{AG}_0^1 = \text{win}] \right| \\ &\quad + \sum_{i=1, \dots, 19} \left| \Pr[\mathbf{AG}_0^i = \text{win}] - \Pr[\mathbf{AG}_0^{i+1} = \text{win}] \right| \\ &\quad + \sum_{i=1, \dots, 19} \left| \Pr[\mathbf{AG}_1^i = \text{win}] - \Pr[\mathbf{AG}_1^{i+1} = \text{win}] \right| \\ &\quad + \left| \Pr[\mathbf{AG}_1^{\text{CCA}} = \text{win}] - \Pr[\mathbf{AG}_1^1 = \text{win}] \right|. \end{aligned}$$

The sequence of games is given in Table 1; by summing up the differences of the winning probabilities, one obtains

$$\begin{aligned} Adv^{(\text{IND} + \text{IK})\text{-CCA-2}^{\text{adap}}}(\mathbf{A}) &\leq (6 \cdot \varepsilon_{\text{PKE-Corr}} + 12 \cdot \varepsilon_{\text{PKE-IND-CPA}} + 8 \cdot \varepsilon_{\text{PKE-IK-CPA}}) \\ &\quad + 2 \cdot (\varepsilon_{\text{NIZK-ZK}} + \varepsilon_{\text{NIZK-Sound}} + 2 \cdot \varepsilon_{\text{NIZK-SS}}) \\ &\quad + 2 \cdot \varepsilon_{\text{SKE-1-IND-CPA}}. \end{aligned}$$

We now justify each game hop in Table 1.

$\mathbf{G}_\beta^{\text{CCA}} \rightsquigarrow \mathbf{G}_\beta^1$ : For  $\beta \in \{0, 1\}$ , one can reduce distinguishing  $\mathbf{G}_\beta^1$  and  $\mathbf{G}_\beta^{\text{CCA}}$  to breaking  $\Pi_{\text{PKE}}$ 's correctness: the reduction holds the secret key of every party and so it can trivially handle any oracle queries. Noting that the reduction only has to query oracle  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{SK}$  on at most  $n \leq n_{\text{PKE}}$  key-pairs, it follows from Equation B.19 that no adversary ( $\varepsilon_{\text{PKE-Corr}}$ )-breaks  $\Pi_{\text{PKE}}$ 's ( $n_{\text{PKE}}$ )-Correctness, implying

$$\left| \Pr[\mathbf{AG}_\beta^{\text{CCA}} = \text{win}] - \Pr[\mathbf{AG}_\beta^1 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}_\beta^1 \rightsquigarrow \mathbf{G}_\beta^2$ : Analogous to  $\mathbf{G}_\beta^{\text{CCA}} \rightsquigarrow \mathbf{G}_\beta^1$ ; it follows

$$\left| \Pr[\mathbf{AG}_\beta^1 = \text{win}] - \Pr[\mathbf{AG}_\beta^2 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}_\beta^2 \rightsquigarrow \mathbf{G}_\beta^3$ : By Equation B.21,  $\Pi_{\text{SKE}}$  is perfectly correct, implying

$$\left| \Pr[\mathbf{AG}_\beta^3 = \text{win}] - \Pr[\mathbf{AG}_\beta^2 = \text{win}] \right| = 0.$$

$\mathbf{G}_\beta^3 \rightsquigarrow \mathbf{G}_\beta^4$ : Similar to  $\mathbf{G}_\beta^{\text{CCA}} \rightsquigarrow \mathbf{G}_\beta^1$ , except that this time the reduction only has to query oracle  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{SK}$  on at most one key-pair; since  $n_{\text{PKE}} \geq 1$  it then follows by Equation B.19 that

$$\left| \Pr[\mathbf{AG}_\beta^4 = \text{win}] - \Pr[\mathbf{AG}_\beta^3 = \text{win}] \right| \leq \varepsilon_{\text{PKE-Corr}}.$$

$\mathbf{G}_\beta^4 \rightsquigarrow \mathbf{G}_\beta^5$ : Note that, for  $\beta \in \{0, 1\}$ , one can reduce distinguishing  $\mathbf{G}_\beta^4$  and  $\mathbf{G}_\beta^5$  to breaking the soundness of the underlying  $\Pi_{\text{NIZK}}$ : since at this point we are assuming perfect correctness of both  $\Pi_{\text{SKE}}$  and  $\Pi_{\text{PKE}}$ , an adversary can only distinguish  $\mathbf{G}_\beta^4$  from  $\mathbf{G}_\beta^5$  if it submits a decryption query for a ciphertext  $c := (p, c_{\text{pp}}, \vec{c}, c_{\text{sym}})$  such that the NIZK proof  $p$  verifies as being valid but the corresponding statement is not true (i.e.  $(1^k, \text{pp.pk}, c_{\text{pp}}, \vec{c}, c_{\text{sym}}) \notin L_{\text{PKEBC}^{\text{adap}}}$ ). In particular, since the reduction holds the secret key of every party  $B_j$ —which consists of  $B_j$ 's public key  $\text{pk}_j$ , the secret bit  $b_j$  and the secret key  $\text{sk}_{b_j}$ —it can handle any secret key queries. Moreover, it also holds the secret key corresponding to the public parameter's public key, it can handle any decryption oracle queries by using the alternative decryption procedure defined in Algorithm 8. Noting that the reduction queries the underlying  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_V$  oracle only once for each  $\mathcal{O}_D$  query, and there are at most  $q_D \leq q_{V\text{NIZK}}$  queries to  $\mathcal{O}_D$ , it follows by Equation B.20

$$|\Pr[\mathbf{AG}_\beta^5 = \text{win}] - \Pr[\mathbf{AG}_\beta^4 = \text{win}]| \leq \varepsilon_{\text{NIZK-Sound}}.$$

$\mathbf{G}_\beta^5 \rightsquigarrow \mathbf{G}_\beta^6$ : It is easy to see that one can reduce distinguishing these two games to breaking  $\Pi_{\text{NIZK}}$ 's Zero-Knowledge, as the reduction holds all secret keys (including the secret key corresponding to  $\text{pp.pk}$ ) and thus can handle any oracle queries. (Although the reduction does not have the trapdoor for the  $\text{crs}$ , in case the  $\text{crs}$  is a simulated one, since it only has to prove true statements it can rely on oracle  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  for generating the necessary NIZK proofs.) Noting the reduction only has to generate at most one NIZK proof for each  $\mathcal{O}_E$  query, since  $q_E \leq q_{P\text{NIZK}}$  it follows from Equation B.20 that no adversary  $(\varepsilon_{\text{NIZK-ZK}}, t_{\text{NIZK}})$ -breaks  $\Pi_{\text{NIZK}}$ 's  $(q_{P\text{NIZK}})$ -ZK, implying

$$|\Pr[\mathbf{AG}_\beta^6 = \text{win}] - \Pr[\mathbf{AG}_\beta^5 = \text{win}]| \leq \varepsilon_{\text{NIZK-ZK}}.$$

$\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ : One can reduce distinguishing  $\mathbf{G}_\beta^7$  and  $\mathbf{G}_\beta^6$  to breaking the IND-CPA security of  $\Pi_{\text{PKE}}$ . In contrast to prior reductions, this time the reduction does not have, for each party  $B_j$ , both  $\text{sk}_0$  and  $\text{sk}_1$ . However, since the scheme itself discards one of the secret keys, namely  $\text{sk}_{\bar{b}}$  (with  $\bar{b} := 1 - b$ ,  $b$  being the bit in the party's secret key), the reduction can still handle  $\mathcal{O}_{SK}$  queries by generating itself the key-pair  $(\text{pk}_b, \text{sk}_b)$  of each party and relying on the underlying oracle  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  to generate public key  $\text{pk}_{\bar{b}}$ . This means the reduction can still handle queries to  $\mathcal{O}_{SK}$ . Regarding queries to  $\mathcal{O}_D$ , the reduction relies on the secret key  $\text{sk}_{\text{pp}}$  corresponding to the public parameters public key as before. Regarding  $\mathcal{O}_E$  queries, note that although the reduction now has to prove NIZK statements that it either does not have a witness for (in  $\mathbf{G}_\beta^6$ ) or are even false (in  $\mathbf{G}_\beta^7$ ), since the NIZK's  $\text{crs}$  is a simulated one generated by the reduction, the reduction holds the  $\text{crs}$  trapdoor  $\tau$  that allows it to simulate NIZK proofs without a witness. Finally, noting that the reduction only queries the underlying  $\Pi_{\text{PKE}}$  IND-CPA security game on at most  $n \leq n_{\text{PKE}}$  different parties and queries  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_E$  at most  $d_E \leq q_{E\text{PKE}}$  times, it follows from Equation B.19 that no adversary  $(\varepsilon_{\text{PKE-IND-CPA}}, t_{\text{PKE}})$ -breaks  $\Pi_{\text{PKE}}$ 's  $(n_{\text{PKE}}, q_{E\text{PKE}})$ -IND-CPA security, implying

$$|\Pr[\mathbf{AG}_\beta^7 = \text{win}] - \Pr[\mathbf{AG}_\beta^6 = \text{win}]| \leq \varepsilon_{\text{PKE-IND-CPA}}.$$

$\mathbf{G}_\beta^7 \rightsquigarrow \mathbf{G}_\beta^8$ : One can reduce distinguishing games  $\mathbf{G}_\beta^8$  and  $\mathbf{G}_\beta^7$  to breaking the IK-CPA security of  $\Pi_{\text{PKE}}$  in a very similar way to the previous step (i.e.  $\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ ). The only difference is in how to handle  $\mathcal{O}_E$  queries: since now we have to swap the public key used for encryption, we cannot simply swap it with another party's public key: on one hand it is crucial the reduction has each party's secret key in order to handle  $\mathcal{O}_{SK}$  queries as before—and thus the reduction cannot simply rely on  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  to create all public keys—and on the other hand, note that when reducing to the IK-CPA security of the underlying  $\Pi_{\text{PKE}}$  scheme, if two parties, say  $B_j$  and  $B_{j'}$  have, respectively, bits  $b_j$  and  $b_{j'}$  in their secret keys, and these bits are such that  $b_j \neq b_{j'}$ , then the reduction cannot simply change the encryption public key of a  $\Pi_{\text{PKE}}$  ciphertext from  $B_j$ 's public key  $\text{pk}_{\bar{b}_j}$  to  $B_{j'}$ 's public key  $\text{pk}_{\bar{b}_{j'}}$ . To avoid this issue we instead use two additional public keys,  $\text{pk}_0$  and  $\text{pk}_1$  in the reduction, that are generated by the underlying  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_{PK}$  oracle and which become the new encryption keys. Since the reduction queries on at most  $n \leq n_{\text{PKE}} - 2$  different parties and queries  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_E$  at most  $d_E \leq q_{E\text{PKE}}$  times, it follows from Equation B.19 that no adversary

$$|\Pr[\mathbf{AG}_\beta^8 = \text{win}] - \Pr[\mathbf{AG}_\beta^7 = \text{win}]| \leq \varepsilon_{\text{PKE-ik-cpa}}.$$

$\mathbf{G}_\beta^8 \rightsquigarrow \mathbf{G}_\beta^9$ : Note that, for any party  $B_j$ , if the adversary makes a query  $\mathcal{O}_E((\vec{V}_0, m_0), (\vec{V}_1, m_1))$ , where  $B_j \in \text{Set}(\vec{V}_0) \cup \text{Set}(\vec{V}_1)$ , then it cannot make any query to  $\mathcal{O}_{SK}$  on  $B_j$ , implying the adversary can never learn the secret bit in  $B_j$ 's secret key. This implies that  $\mathbf{G}_\beta^9$  is perfectly indistinguishable from  $\mathbf{G}_\beta^8$ . Hence

$$|\Pr[\mathbf{AG}_\beta^9 = \text{win}] - \Pr[\mathbf{AG}_\beta^8 = \text{win}]| = 0.$$

$\mathbf{G}_\beta^9 \rightsquigarrow \mathbf{G}_\beta^{10}$ : Analogous to  $\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ .

$\mathbf{G}_\beta^{10} \rightsquigarrow \mathbf{G}_\beta^{11}$ : Analogous to  $\mathbf{G}_\beta^7 \rightsquigarrow \mathbf{G}_\beta^8$ .

$\mathbf{G}_\beta^{11} \rightsquigarrow \mathbf{G}_\beta^{12}$ : Note that one can reduce distinguishing these two games to breaking the 1-IND-CPA security of the underlying  $\Pi_{\text{SKE}}$  scheme: since the reduction holds exactly the same information as it did in the last few games, it can handle both decryption oracle queries and secret key queries as before. Given that for each query to  $\mathcal{O}_E$  the reduction queries  $\Pi_{\text{SKE}}\text{-}\mathcal{O}_E$  at most once, by Equation B.21 it follows

$$|\Pr[\mathbf{AG}_\beta^{12} = \text{win}] - \Pr[\mathbf{AG}_\beta^{11} = \text{win}]| \leq \varepsilon_{\text{SKE-1-ind-cpa}}.$$

$\mathbf{G}_\beta^{12} \rightsquigarrow \mathbf{G}_\beta^{13}$ : Analogous to  $\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ .

$\mathbf{G}_\beta^{13} \rightsquigarrow \mathbf{G}_\beta^{14}$ : Analogous to  $\mathbf{G}_\beta^7 \rightsquigarrow \mathbf{G}_\beta^8$ .

$\mathbf{G}_\beta^{14} \rightsquigarrow \mathbf{G}_\beta^{15}$ : Analogous to  $\mathbf{G}_\beta^8 \rightsquigarrow \mathbf{G}_\beta^9$ .

$\mathbf{G}_\beta^{15} \rightsquigarrow \mathbf{G}_\beta^{16}$ : Analogous to  $\mathbf{G}_\beta^6 \rightsquigarrow \mathbf{G}_\beta^7$ .

$\mathbf{G}_\beta^{16} \rightsquigarrow \mathbf{G}_\beta^{17}$ : Analogous to  $\mathbf{G}_\beta^7 \rightsquigarrow \mathbf{G}_\beta^8$ .

$\mathbf{G}_\beta^{17} \rightsquigarrow \mathbf{G}_\beta^{18}$ : This step is similar to  $\mathbf{G}_\beta^4 \rightsquigarrow \mathbf{G}_\beta^5$ , except that now the reduction has to prove a false NIZK statement each time  $\mathcal{O}_E$  is queried. Although the reduction does not have the trapdoor to the simulated  $\mathbf{crs}$ , it can rely on the  $\Pi_{\text{NIZK}}\text{-}\mathcal{O}_P$  oracle to obtain these proofs. As before, since the reduction holds the secret key of every party, it can handle any oracle queries. Given the reduction only has to generate one NIZK proof for each  $\mathcal{O}_E$  query, and only has to verify one NIZK proof for each  $\mathcal{O}_D$  query, since there are at most  $q_E \leq q_{P_{\text{NIZK}}}$  queries to  $\mathcal{O}_E$  and  $q_D \leq q_{V_{\text{NIZK}}}$  queries to  $\mathcal{O}_D$ , it follows by Equation B.20

$$|\Pr[\mathbf{AG}_\beta^{18} = \text{win}] - \Pr[\mathbf{AG}_\beta^{17} = \text{win}]| \leq \varepsilon_{\text{NIZK-SS}}.$$

$\mathbf{G}_\beta^{18} \rightsquigarrow \mathbf{G}_\beta^{19}$ : Note that one can reduce distinguishing  $\mathbf{G}_\beta^{19}$  and  $\mathbf{G}_\beta^{18}$  to breaking the IND-CPA security of  $\Pi_{\text{PKE}}$ . Noting that the reduction only queries the underlying security game for one public key—namely  $\text{pp.pk}$ —and since the reduction queries the underlying  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_E$  oracle at most  $d_E \leq q_{E_{\text{PKE}}}$  times, it follows from Equation B.19

$$|\Pr[\mathbf{AG}_\beta^{19} = \text{win}] - \Pr[\mathbf{AG}_\beta^{18} = \text{win}]| \leq \varepsilon_{\text{PKE-IND-CPA}}.$$

$\mathbf{G}_\beta^{19} \rightsquigarrow \mathbf{G}_\beta^{20}$ : Analogous to  $\mathbf{G}_\beta^{18} \rightsquigarrow \mathbf{G}_\beta^{19}$ , except that the reduction only queries the underlying  $\Pi_{\text{PKE}}\text{-}\mathcal{O}_E$  oracle at most  $q_E \leq q_{E_{\text{PKE}}}$  times.

To conclude the proof, note that each reduction simply has to emulate the original game towards  $\mathbf{A}$ —with a few tweaks that, apart from the generation of a simulated  $\mathbf{crs}$  and the generation of simulated NIZK proofs, do not affect the time for emulating the game. Letting  $t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}$  be the time to run  $\Pi$ 's  $\mathbf{G}_\beta^{\text{CCA}}$  game experiment (with  $\beta \in \{0, 1\}$ ),  $t_{S_P}$  be the runtime of  $S_P$  and  $t_{S_G}$  be the runtime of  $S_G$ , it follows

$$\begin{aligned} t_{\text{PKE}}, t_{\text{SKE}} &\approx t + t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}} + q_E \cdot t_{S_P} + t_{S_G}, \\ t_{\text{NIZK}} &\approx t + t_{(\text{IND+IK})\text{-CCA-2}^{\text{adap}}}. \end{aligned}$$

□

Table 1: Sequence of hybrids for proving the (IND + IK)-CCA-2 security of our scheme. The first row specifies, for  $\beta \in \{0, 1\}$ ,  $\mathbf{G}_\beta^{\text{CCA}}$ ; each of the following rows specifies a hybrid game  $\mathbf{G}_\beta^i$ , with  $\beta \in \{0, 1\}$ . The  $\varepsilon$  column indicates, for each row, an upper bound in an adversary's advantage in distinguishing between that row's game and the previous row's game. The non-shaded cell of each row specifies how the hybrid differs from the previous game (except for the first row, which specifies  $\mathbf{G}_\beta^{\text{CCA}}$ ). Columns: NIZK: indicates whether the  $\text{crs}$  output by  $\mathcal{O}_{PP}$  and the proofs output by  $\mathcal{O}_E$  queries are real ones (Real) or simulated ones (Sim);  $\mathcal{O}_D$ : indicates how the game handles decryption queries— $c_{\text{sym}}$  indicates that the game handles decryption queries by following the normal decryption procedure, whereas  $c_{\text{pp}}$  indicates that the game handles decryption queries by following the alternative decryption procedure (see Algorithm 8);  $\mathcal{O}_E$ : indicates how  $\mathcal{O}_E$  queries are handled—columns named Value indicate what value is encrypted (by the part of the ciphertext corresponding to that column), and columns named pk indicate what public key is used (by the part of the ciphertext corresponding to that column); Correctness: columns  $\text{pp.pk}$ ,  $\text{pk}_j.\text{pk}_0$  and  $\text{pk}_j.\text{pk}_1$  indicate whether the  $\Pi_{\text{PKE}}$  key pairs (corresponding to the columns public key) are correct; column  $\Pi_{\text{SKE}}$  indicates whether  $\Pi_{\text{SKE}}$  is assumed to be perfectly correct. In columns  $c_{i,b,1}$ ,  $c_{i,\bar{b},1}$ ,  $c_{i,b,2}$  and  $c_{i,\bar{b},2}$  under  $\mathcal{O}_E$ ,  $b$  denotes the bit of the secret key of  $V_{\beta,i}$ , and  $\bar{b}$  denotes the complement of  $b$ , i.e.  $\bar{b} := 1 - b$ . In the table,  $\text{pk}_0$  and  $\text{pk}_1$  are two  $\Pi_{\text{PKE}}$  public keys that are (honestly) sampled independently from all parties' public keys and independently from  $\text{pp.pk}$ ; these public keys are only used for the IK-CPA security reductions. Finally, all values 0 under columns Value are assumed to have appropriate length. For instance, in  $\mathbf{G}_\beta^7$  the 0 is assumed to be of the same length as  $k_{\text{sym}}$ , and in  $\mathbf{G}_\beta^{12}$  the 0 is assumed to be of the same length as  $(\vec{v}_\beta, m_\beta)$ .

## C Gaps in Security Proofs of Prior Work

In [6], Damgård et al. introduce an intermediate type of scheme, Provably Simulatable Designated Verifier Signature (PSDVS) schemes, from which they then construct a full-fledged MDVS scheme (see [6, Construction 1]). In this section we provide details on two proof gaps: one in the proof of [6, Theorem 2]—the theorem establishing the security of their PSDVS-based MDVS construction—and one in the proof of [6, Theorem 3]—the theorem establishing the security of their PSDVS construction based on standard primitives.

*Issue with Consistency Proof of MDVS Construction from Standard Primitives.* The Consistency security notion given in [6, Definition 2] provides adversaries with access to a signature verification oracle. Unfortunately, in the proof of [6, Theorem 2]—the security proof establishing the security of their MDVS scheme construction from PSDVS schemes (see [6, Construction 1])—it is not mentioned how the reduction could handle signature verification queries. Furthermore, it is also not clear how such queries could be handled, as the security notions for the PSDVS scheme on which the consistency proof relies (see [6, Definitions 10, 13 and 15]) do not themselves provide an adversary with access to a verification oracle either. Finally, we would like to note that it is desirable to provide the adversary with access to such an oracle since signatures are not publicly verifiable; in particular, the composable treatment of MDVS schemes given in [16] requires the consistency game to provide access to a signature verification oracle.

*Issue with Verifier Signature Simulation Indistinguishability Proof of the PSDVS Construction from Standard Primitives.* In the proof of [6, Theorem 3]—which establishes the security of [6, Construction 2], the PSDVS construction from standard primitives—and in particular in paragraph “VerSigSim Indistinguishability, (Definition 11)”, it is argued that verifier simulated signatures are indistinguishable from real signatures generated by the signer due to the pseudorandomness of the PRF underlying their construction. Unfortunately, the PRF’s secret seed is part of the verifier’s secret key, and, according to [6, Definition 11], the adversary has access to the verifier’s secret key, making it unclear how one could actually make a reduction to the pseudorandomness of the underlying PRF.
