Abstract

Common random string model is a popular model in classical cryptography with many constructions proposed in this model. We study a quantum analogue of this model called the common Haar state model, which was also studied in an independent work by Chen, Coladangelo and Sattath (arXiv 2024). In this model, every party in the cryptographic system receives many copies of one or more i.i.d Haar states.

Our main result is the construction of a statistically secure PRSG with: (a) the output length of the PRSG is strictly larger than the key size, (b) the security holds even if the adversary receives $O\left(\frac{\lambda}{(\log(\lambda))^{0.01}}\right)$ copies of the pseudorandom state. We show the optimality of our construction by showing a matching lower bound. Our construction is simple and its analysis uses elementary techniques.

1 Introduction

In classical cryptography, the common random string and the common reference string models were introduced to tackle cryptographic tasks that were impossible to achieve in the plain model. In the common reference string model, there is a trusted setup who produces a string that every party has access to. In the common random string model, the common string available to all the parties is sampled uniformly at random, thus avoiding the need for a trusted setup. As a result, the common random string model is the more desirable model of the two. There have been many constructions proposed over the years in these two models, including non-interactive zero-knowledge [BFM19], secure computation secure under universal composition [CF01; CLOS02] and two-round secure computation [GS22; BL18].

It is a worthy pursuit to study similar models for quantum cryptographic protocols. In this case, there is an option to define models that are inherently quantum. For instance, we could define a model wherein a trusted setup produces a quantum state and every party participating in the cryptographic system receives one or many copies of this quantum state. Indeed, two works by Morimae, Nehoran and Yamakawa [MNY23] and Qian [Qia23] consider this model, termed as the common quantum reference string model (CQRS). They proposed unconditionally secure commitments in this model. Quantum commitments is a foundational notion in quantum cryptography. In recent years, quantum commitments have been extensively studied [AQY22; MY21; AGQY22; BCQ22; Bra23] due to its implication to secure computation [BCKM21; GLSV21]. The fact that information-theoretically secure commitments are impossible in the plain model [LC97; May97; CLM23] makes the contributions of [MNY23; Qia23] quite interesting.

While CQRS is a quantum analogue of common reference string model, we can ask if there is a quantum analogue of the common random string model. An independent and concurrent recent work by Chen, Coladangelo and Sattath [CCS24] (henceforth, referred to as CCS) introduced a model, called the common Haar random state model (CHRS). In this model, every party in the system receives many copies of many i.i.d Haar states. They presented constructions of pseudorandomness and commitments in this model. The goal of our work is to study this model further.

Our Work. We consider a simpler version of the common Haar random state model, wherein every party receives many copies of one Haar state. Feasibility results in our model are stronger than the model considered by CCS whereas the negative results would be weaker. We call our model the common Haar state model (CHS).

Similar to CCS, we present constructions of pseudorandom states and commitments in the CHS model.

Statistical Pseudorandom States (i.e., State Designs): The concept of pseudorandom state generators (PRSGs) was introduced in a seminal work by Ji, Liu and Song [JLS18]. Roughly speaking, it states that any computationally bounded adversary cannot distinguish whether it receives many copies of a state produced using a pseudorandom state generator on a uniform key versus many copies of a single Haar state. Constructions of pseudorandom states are known from one-way functions [JLS18; BS19; AGQY22; JMW23; GB23]. It is known that for a broad range of parameters, we need to impose the restriction that the adversary is computationally bounded [AGQY22]. One such case is when the output length of the state generator is larger than the length of the key; referred to as stretch PRSGs. In this case, even if the adversary gets one copy of the state then it can break the pseudorandomness property if it is unbounded.

We consider the possibility of statistically secure stretch PRSGs. We show the following. In the theorem below, we denote \( \lambda \) to be the key length of the PRSG.

**Theorem 1.1 (Informal).** There is a statistically secure PRSG in the CHS model satisfying the following: (a) the output length of PRSG is \( > \lambda \) and, (b) the security holds as long as the adversary receives \( O \left( \frac{\lambda}{\log(\lambda)^{1+\epsilon}} \right) \) copies, for some constant \( \epsilon > 0 \).

This improves upon CCS [CCS24] who only showed 1-copy stretch PRSG exists in their model. Moreover, our construction and in particular, our analysis, is arguably simpler and elementary compared to CCS. Another advantage of our work is that we can achieve arbitrary stretch whereas it is unclear whether this is
also achieved by CCS. As a side contribution, the proof of our PRSG construction also simplifies the proof of the quantum public-key construction of Coladangelo [Col23]; this is due to the fact the core lemma proven in [Col23] is a paraphrased version of the above theorem.

Interestingly, both works design PRSGs which only consume one copy of a single Haar state. In this special case, it is interesting to understand whether we can extend our result to the setting when the adversary receives \( O\left(\frac{1}{\log(\lambda)}\right) \) copies. We show this is not possible.

**Theorem 1.2** (Informal). There does not exist a secure PRSG in the CHS model satisfying the following: (a) the PRSG uses only one copy of the Haar state in the CHS model, (b) the adversary receives \( \Omega\left(\frac{1}{\log(\lambda)}\right) \) copies of the pseudorandom state and, (c) the output length is \( \omega(\log(\lambda)) \).

CCS also proved a lower bound where they showed that unbounded copy pseudorandom states do not exist. Their negative result is stronger in the sense that they rule out PRSGs who use up many copies of the Haar states from the CHRS. On the other hand, for the special case when the PRSG only takes one copy of the Haar state, we believe our result yields better parameters.

**Commitments:** We show the following.

**Theorem 1.3** (Informal). There is an unconditionally secure bit commitment scheme in the CHS model.

Both our construction and the commitments scheme proposed by CCS are different although they share strong similarities. Even the proof techniques seem to be similar.

**Future Directions.** The work by [CCS24] and our work initiates an interesting research direction: to build cryptography in the common Haar state model. It would be interesting to the feasibility of other cryptographic constructions in this model. It would also be interesting to understand other variants of this model. One such variant is the Haar random oracle model, studied by [BFV19; CM21]. We leave open the question of investigating the relationship between these different models and also developing toolkits that will aid us in proving (in)feasibility results in these models.

## 2 Preliminaries

We denote the security parameter by \( \lambda \). We assume that the reader is familiar with the fundamentals of quantum computing covered in [NC10].

### 2.1 Notation

- We use \([n]\) to denote \(\{1, \ldots, n\}\) and \([0 : n]\) to denote \(\{0, 1, \ldots, n\}\).
- We denote \(S_t\) to be the symmetric group of degree \(t\).
- For a set \(A\) and \(t \in \mathbb{N}\), we define \(A^t := \{(a_1, \ldots, a_t) : \forall i \in \{t\}, a_i \in A\}\).
- For \(\sigma \in S_t\) and \(v = (v_1, \ldots, v_t)\), we define \(\sigma(v) := (v_{\sigma(1)}, \ldots, v_{\sigma(t)})\).
- We use \(D(H)\) to denote the set of density matrices in the Hilbert space \(H\).
- Let \(\rho_{AB} \in D(H_A \otimes H_B)\), by \(\text{Tr}_B(\rho_{AB}) \in D(H_A)\) we denote the reduced density matrix by taking partial trace over \(B\).
- We denote the trace distance between quantum states \(\rho, \rho'\) by \(\text{TD}(\rho, \rho') := \frac{1}{2}\|\rho - \rho'\|_1\).
- We denote the Haar measure over \(n\) qubits by \(\mathcal{H}_n\).
2.2 Pseudorandom State Generators

We recall the definition of statistical pseudorandom state generators (PRS).

**Definition 2.1.** We say that a QPT algorithm $G$ is an $\ell$-copy statistical PRS generator if the following holds:

- **State Generation:** For any $\lambda \in \mathbb{N}$ and $k \in \{0, 1\}^\lambda$, the algorithm $G$ is a quantum channel that satisfies
  $$G(|k\rangle) = |\psi_k\rangle\langle\psi_k|,$$
  for some $n(\lambda)$-qubit state $|\psi_k\rangle$.
- **Psuedorandomness:** For any computationally unbounded adversary $A$, there exists a negligible function $\text{negl}(\cdot)$ such that:
  $$\Pr_{k \leftarrow \{0, 1\}^\lambda} [A_\lambda (G(|k\rangle)^{\otimes \ell}) = 1] - \Pr_{|\varphi\rangle \leftarrow \mathcal{H}_n} [A_\lambda (|\varphi\rangle^{\otimes \ell}) = 1] \leq \text{negl}(\lambda).$$

If $G$ satisfies the above security definition for every polynomial $\ell$, we say that $G$ is an unbounded poly-copy statistical PRS generator.

2.3 Quantum Commitments

We recall the definition of commitment schemes in the CRQS model [MNY23].

**Definition 2.2** (Quantum commitments in the Common Reference Quantum State (CRQS) model [MNY23]). A (non-interactive) quantum commitment scheme in the CRQS model is given by a tuple of the setup algorithm $\text{Setup}$, committer $C$, and receiver $R$, all of which are uniform QPT algorithms. The scheme is divided into three phases, the setup phase, commit phase, and reveal phase as follows:

- **Setup phase:** $\text{Setup}$ takes $1^\lambda$ as input, uniformly samples a classical key $k \leftarrow K_\lambda$, generates two copies of the same pure state $|\psi_k\rangle$ and sends one copy each to $C$ and $R$.
- **Commit phase:** $C$ takes $|\psi_k\rangle$ given by the setup algorithm and a bit $b \in \{0, 1\}$ to commit as input, generates a quantum state on registers $C$ and $R$, and sends the register $C$ to $R$.
- **Reveal phase:** $C$ sends $b$ and the register $R$ to $R$. $R$ takes $|\psi_k\rangle$ given by the setup algorithm and $(b, C, R)$ given by $C$ as input, and outputs $b$ if it accepts and otherwise outputs $\perp$.

**Definition 2.3** ($t$-copy statistical hiding [MNY23]). A quantum commitment scheme $(\text{Setup}, C, R)$ in the CRQS model satisfies $t$-copy statistical hiding if for any non-uniform unbounded-time algorithm $A$,

$$\Pr \left[ A(1^\lambda, |\psi_k\rangle^{\otimes t}, \text{Tr}_R(\sigma_{CR})) = 1 : \sigma_{CR} \leftarrow C_{\text{com}}(|\psi_k\rangle, 0) \right] - \Pr \left[ A(1^\lambda, |\psi_k\rangle^{\otimes t}, \text{Tr}_R(\sigma_{CR})) = 1 : \sigma_{CR} \leftarrow C_{\text{com}}(|\psi_k\rangle, 1) \right] \leq \text{negl}(\lambda),$$

where $C_{\text{com}}$ is the commit phase of $C$.

**Definition 2.4** (Statistical sum-binding [MNY23]). A quantum commitment scheme $(\text{Setup}, C, R)$ in the CQRS model satisfies statistical sum-binding if the following holds. For any pair of non-uniform unbounded-time malicious committers $C^*_b$ and $C^*_1$ that take the classical key $k$, which is sampled by the setup algorithm, as input and work in the same way in the commit phase, if we let $p_b$ to be the probability that $R$ accepts the revealed bit $b$ in the interaction with $C^*_b$ for $b \in \{0, 1\}$, then we have

$$p_0 + p_1 \leq 1 + \text{negl}(\lambda).$$
2.4 Common Haar State Model

The Common Haar State (CHS) model is a variant of the Common Reference Quantum State (CRQS) model. In this model, all parties receive polynomially many copies of a qubit state sampled from the Haar distribution.

2.4.1 Pseudorandom State Generators in the CHS model

**Definition 2.5** ($\ell$-copy PRS in CHS model). Let $|\vartheta\rangle$ denote the $n(\lambda)$-qubit common Haar state. We say that a QPT algorithm $G$ is an $\ell$-copy statistical PRS generator in the CHS model if the following holds:

- **State Generation**: For any $\lambda \in \mathbb{N}$ and $k \in \{0,1\}^{\lambda}$, the algorithm $G_k$ (where $G_k$ denotes $G(k, \cdot)$) is a quantum channel such that for every $n$-qubit state $|\vartheta\rangle$,

  $G_k(|\vartheta\rangle\langle\vartheta|) = |\vartheta_k\rangle\langle\vartheta_k|,$

  for some $n$-qubit state $|\vartheta_k\rangle$. We sometimes write $G_k(|\vartheta\rangle)$ for brevity.\(^1\)

- **Pseudorandomness**: For any polynomial $t(\cdot)$ and computationally unbounded adversary $A$, there exists a negligible function $\text{negl}(\cdot)$ such that:

  $$\left| \Pr_{k \leftarrow \{0,1\}^{\lambda}} \left[ A_{\lambda} \left( G_k(|\vartheta\rangle)^{\otimes \ell}, |\vartheta\rangle^{\otimes t} \right) = 1 \right] - \Pr_{|\varphi\rangle \leftarrow \mathcal{H}_n, |\vartheta\rangle \leftarrow \mathcal{H}_n} \left[ A_{\lambda} \left( |\varphi\rangle^{\otimes \ell}, |\vartheta\rangle^{\otimes t} \right) = 1 \right] \right| \leq \text{negl}(\lambda).$$

We define a stronger variant of the above notion called a multi-key $\ell$-copy PRS generator. Looking ahead, our construction of PRS in Section 3.1 satisfies this stronger definition. In addition, we show in Section 4 that multi-key 1-copy stretch PRS generator in the CHS model implies statistically hiding, statistically sum-binding commitments in the CHS model.

**Definition 2.6** (Multi-key $\ell$-copy PRS in CHS model). Let $|\vartheta\rangle$ denote the $n(\lambda)$-qubit common Haar state. We say that a QPT algorithm $G$ is a multi-key $\ell$-copy statistical PRS generator in the CHS model if the following holds:

- **State Generation**: For any $\lambda \in \mathbb{N}$ and $k \in \{0,1\}^{\lambda}$, the algorithm $G_k$ (where $G_k$ denotes $G(k, \cdot)$) is a quantum channel such that for every $n$-qubit state $|\vartheta\rangle$,

  $G_k(|\vartheta\rangle\langle\vartheta|) = |\vartheta_k\rangle\langle\vartheta_k|,$

  for some $n$-qubit state $|\vartheta_k\rangle$. We sometimes write $G_k(|\vartheta\rangle)$ for brevity.

- **Multi-key Pseudorandomness**: For any polynomial $t(\cdot)$, $p(\cdot)$ and computationally unbounded adversary $A$, there exists a negligible function $\text{negl}(\cdot)$ such that:

  $$\left| \Pr_{k_1, \ldots, k_p \leftarrow \{0,1\}^{\lambda}} \left[ A_{\lambda} \left( \otimes_{i=1}^p G_k_i(|\vartheta\rangle)^{\otimes \ell}, |\vartheta\rangle^{\otimes t} \right) = 1 \right] - \Pr_{|\varphi_1\rangle, \ldots, |\varphi_p\rangle \leftarrow \mathcal{H}_n} \left[ A_{\lambda} \left( \otimes_{i=1}^p |\varphi_i\rangle^{\otimes \ell}, |\vartheta\rangle^{\otimes t} \right) = 1 \right] \right| \leq \text{negl}(\lambda).$$

**Remark 2.7.** Note that in the plain model, PRS implies multi-key PRS because the PRS does not share randomness for different keys. This is not trivially true in CHS model as the generator for all keys shares the same common Haar state.

\(^1\)More generally, the generation algorithm could take multiple copies of the common Haar state as input or output a state of size different from the CHS but we focus on generation algorithms taking only one copy of the Haar state and the output of the generator is the same size as the CHS.
2.4.2 Quantum Commitments in the CHS model

Definition 2.8 (Quantum commitments in the Common Haar State (CHS) model). A (non-interactive) quantum commitment scheme in the CHS model is given by a tuple of the committer $C$ and receiver $R$, all of which are uniform QPT algorithms. Let $|\theta\rangle$ be the $n(\lambda)$-qubit common Haar state. The scheme is divided into two phases, commit phase, and reveal phase as follows:

- Commit phase: $C$ takes $|\theta\rangle \otimes p$ for some polynomial $p(\cdot)$ and a bit $b \in \{0, 1\}$ to commit as input, generates a quantum state on registers $C$ and $R$, and sends the register $C$ to $R$.

- Reveal phase: $C$ sends $b$ and the register $R$ to $R$. $R$ takes $|\theta\rangle \otimes p$ and $(b, C, R)$ given by $C$ as input, and outputs $b$ if it accepts and otherwise outputs $\perp$.

Definition 2.9 (Poly-copy statistical hiding). A quantum commitment scheme $(C, R)$ in the CHS model satisfies poly-copy statistical hiding if for any non-uniform unbounded-time algorithm $A$, and any polynomial $t(\cdot)$, there exists a negligible function $\text{negl}(\cdot)$ such that

\[
\left| \Pr \left[ A(1^\lambda, |\theta\rangle \otimes T, Tr_R(\sigma_{CR})) = 1 : \sigma_{CR} \leftarrow C_{\text{com}}(|\theta\rangle \otimes p, 0) \right] - \Pr \left[ A(1^\lambda, |\theta\rangle \otimes T, Tr_R(\sigma_{CR})) = 1 : \sigma_{CR} \leftarrow C_{\text{com}}(|\theta\rangle \otimes p, 1) \right] \right| \leq \text{negl}(\lambda),
\]

where $C_{\text{com}}$ is the commit phase of $C$.

Definition 2.10 (Statistical sum-binding). A quantum commitment scheme $(C, R)$ in the CHS model satisfies statistical sum-binding if the following holds. For any pair of non-uniform unbounded-time malicious committers $C_0^*$ and $C_1^*$ that take $|\theta\rangle \otimes T$ for arbitrary large $T(\cdot)$ as input and work in the same way in the commit phase, if we let $p_0$ be the probability that $R$ accepts the revealed bit $b$ in the interaction with $C_0^*$ for $b \in \{0, 1\}$, then we have

\[
p_0 + p_1 \leq 1 + \text{negl}(\lambda).
\]

2.5 Symmetric Subspaces, Type States, and Haar States

The proof of facts and lemmas in this subsection can be found in [Har13]. Let $v = (v_1, \ldots, v_t) \in A^t$ for some finite set $A$. Let $|A| = N$. Define $\text{type}(v) = (0 : t)^N$ to be the type vector such that the $i$th entry of $\text{type}(v)$ equals the number of occurrences of $i \in [N]$ in $v$.

In this work, by $T \in [0 : t]^N$, we implicitly assume that $\sum_{i \in [N]} T_i = t$. For $T \in [0 : t]^N$, we denote by $\text{mset}(T)$ the multiset uniquely determined by $T$. That is, the multiplicity of $i \in \text{mset}(T)$ equals $T_i$ for all $i \in [N]$. We write $T \leftarrow [0 : t]^N$ to mean sampling $T$ uniformly from $[0 : t]^N$ conditioned on $\sum_{i \in [N]} T_i = t$. We write $v \leftarrow T$ to mean $v \in A^t$ satisfies $\text{type}(v) = T$.

In this work, we will focus on collision-free types $T$ which satisfy $T_i \in \{0, 1\}$ for all $i \in [N]$. A collision-free type $T$ can be naturally treated as a set and we write $v \leftarrow T$ to mean sampling a uniform $v$ conditioned on $\text{type}(v) = T$.

Definition 2.11 (Type states). Let $T \in [0 : t]^N$, we define the type states:

\[
|T| := \sqrt{\frac{\prod_{i \in [N]} T_i!}{t!}} \sum_{v \in T} |v\rangle.
\]

If $T$ is collision-free, then it can be simplified to

\[
|T| = \frac{1}{\sqrt{t!}} \sum_{v \in T} |v\rangle.
\]

\footnote{We identify $[0 : t]^N$ as $[0 : t]^t$.}
Furthermore, it has the following useful expression

$$|T\rangle\langle T| = \frac{1}{\ell!} \sum_{\nu, \mu \in T} |\nu\rangle\langle \mu| = \mathbb{E}_{\mathcal{V} \rightarrow T} \left[ \sum_{\sigma \in S_t} |\nu\rangle\langle \sigma(\nu)| \right].$$  \hspace{1cm} (1)

**Lemma 2.12** (Average of copies of Haar-random states). For all $N, t \in \mathbb{N}$, we have

$$\mathbb{E}_{|\theta| \in \mathcal{H}(CN)} |\theta\rangle\langle \theta|^{\otimes t} = \mathbb{E}_{T \rightarrow [0:t]^n} |T\rangle\langle T|. $$

**Definition 2.13** ($\ell$-fold $n$-prefix collision-free types). Let $n, m, t, \ell \in \mathbb{N}$ such that $t \geq \ell$ and $T \in [0 : t]^{2n+m}$. We say $T$ is a $\ell$-fold $n$-prefix collision-free if for all pairs of $\ell$-subsets $S, T \subseteq \text{mset}(T)$, the first $n$ bits of $\bigoplus_{x \in S} x \in \{0, 1\}^{n+m}$ is identical to that of $\bigoplus_{y \in T} y \in \{0, 1\}^{n+m}$ if and only if $S = T$. We define $\mathcal{I}_{n,m}^{(\ell)} := \{ T \in [0 : t]^{n+m} : T \text{ is } \ell \text{-fold } n \text{-prefix collision-free} \}$.

For a fixed $t$, one can easily verify that $\ell$-fold $n$-prefix collision-freeness implies $\ell'$-fold $n$-prefix collision-freeness for $\ell > \ell'$, and 1-fold $n$-prefix collision-freeness is equivalent to the standard collision-freeness.

**Lemma 2.14.** If $\ell = \Theta(2^n)$, then $\Pr_{T \rightarrow [0:t]^{2n+m}} [T \in \mathcal{I}_{n,m}^{(\ell)}] = 1 - O(t^{2\ell}/2^n)$.

**Proof.** First, sampling $T \leftarrow [0 : t]^{2n+m}$ uniformly is $O(t^2/2^{n+m})$-close to sampling a uniform collision-free $T$ from $[0 : t]^{2n+m}$ by collision bound. Furthermore, sampling a uniform collision-free $T$ from $[0 : t]^{2n+m}$ is equivalent to sampling $t$ elements $x_1, x_2, \ldots, x_t$ one by one from $\{0, 1\}^{n+m}$ conditioned on them being distinct and setting $T$ such that $\text{mset}(T) = \{x_1, \ldots, x_t\}$. Hence, it suffices to show that sampling $t$ elements $x_1, x_2, \ldots, x_t$ one by one from $\{0, 1\}^{n+m}$ conditioned on them being distinct results in an $\ell$-fold $n$-prefix collision-free set with probability $1 - O(t^{2\ell}/2^n)$.

For any two distinct $\ell$-subsets of indices $S \neq T \subseteq [t]$, let $\text{Bad}_{S, T}$ denote the event that the first $n$ bits of $\bigoplus_{i \in S} x_i$ is the same as that of $\bigoplus_{j \in T} x_j$. Then $\Pr \left[ \text{Bad}_{S, T} : x_1, x_2, \ldots, x_t \in \{0, 1\}^{n+m}, \text{ all distinct} \right] = O(1/2^n - 2\ell)$. This is because we can first sample $|S \cup T| - 1$ elements (in $S \cup T$) except one with indices in $S \setminus T$. Then $\text{Bad}_{S, T}$ occurs only if the first $n$ bits of the last sample is equal to the first $n$ bits of the bitwise XOR of all other elements in $S$ with all elements in $T$, which happens with probability at most $O(1/(2^n - 2\ell))$. By a union bound, we have $T \in \mathcal{I}_{n,m}^{(\ell)}$ with probability one but $O(t^{2\ell}/2^{n+m}) + \binom{t}{\ell} \cdot O(1/(2^n - 2\ell)) = O(t^{2\ell}/2^n)$. \hfill $\square$

**Lemma 2.15.** For any $\nu \in \{0, 1\}^{(n+m)t}$ such that $\text{type}(\nu) \in \mathcal{I}_{n,m}^{(\ell)}$ and $\sigma \in S_t$, define

$$A_{\nu, \sigma} := \mathbb{E}_{k \in [0, 1)^n} \left[ \left( \sum_{i=1}^{\ell} \nu_{k^i} \oplus \nu_{k^{i+\ell}} \right) \cdot |\nu\rangle\langle \sigma(\nu)| \cdot \left( \sum_{i=1}^{\ell} \nu_{k^i} \oplus \nu_{k^{i+\ell}} \right) \right]. $$

Then $A_{\nu, \sigma} = |\nu\rangle\langle \sigma(\nu)|$ if $\sigma$ maps $[\ell]$ to $[\ell]$; otherwise, $A_{\nu, \sigma} = 0$.

**Proof.** Suppose $\nu = (v_1||w_1, \ldots, v_t|w_t) \in \{0, 1\}^{(n+m)t}$ with $v_i \in \{0, 1\}^n$ and $w_i \in \{0, 1\}^m$ for all $i \in [t]$. First, a direct calculation yields

$$\left( \sum_{i=1}^{\ell} \nu_{k^i} \oplus \nu_{k^{i+\ell}} \right) |\nu\rangle\langle \sigma(\nu)| \left( \sum_{i=1}^{\ell} \nu_{k^i} \oplus \nu_{k^{i+\ell}} \right) = (-1)^{(k, \oplus_{i=1}^{\ell} (v_i \oplus w_{\sigma(i)}))} |\nu\rangle\langle \sigma(\nu)|.$$ 

Therefore, after averaging over $k$,

$$A_{\nu, \sigma} = \mathbb{E}_{k \in [0, 1)^n} \left[ (-1)^{(k, \oplus_{i=1}^{\ell} (v_i \oplus w_{\sigma(i)}))} |\nu\rangle\langle \sigma(\nu)| \right] = \begin{cases} |\nu\rangle\langle \sigma(\nu)| & \text{if } \oplus_{i=1}^{\ell} (v_i \oplus w_{\sigma(i)}) = 0 \\ 0 & \text{otherwise.} \end{cases}$$

Since $\text{type}(\nu) \in \mathcal{I}_{n,m}^{(\ell)}$, the condition $\oplus_{i=1}^{\ell} v_i = \oplus_{i=1}^{\ell} w_{\sigma(i)}$ holds if and only if the two sets $\{1, 2, \ldots, \ell\}$ and $\{\sigma(1), \sigma(2), \ldots, \sigma(\ell)\}$ are identical. \hfill $\square$
The following lemma lies in the technical heart of this work. It says that the action of applying random $Z^k$ on $\ell$-fold $n$-prefix collision-free types $T$ has the following “classical” probabilistic interpretation: the output is identically distributed to first uniformly sampling an $\ell$-subset $X \subset T$ and then outputting $|X\rangle \langle X| \otimes |T \setminus X\rangle \langle T \setminus X|$.

**Lemma 2.16.** For any $T \in T_{n,m}^{(\ell)}(t)$,

$$
\mathbb{E}_{k \in \{0,1\}^n} \left[ \left( (Z^k \otimes I_m)^{\otimes \ell} \otimes I_{n+m}^{\otimes t-\ell} \right) |T\rangle \langle T| \left( (Z^k \otimes I_m)^{\otimes \ell} \otimes I_{n+m}^{\otimes t-\ell} \right) \right] = \mathbb{E}_{X \subset T} \left[ |X\rangle \langle X| \otimes |T \setminus X\rangle \langle T \setminus X| \right],
$$

where $X$ is a uniform $\ell$-subset of $T$.

**Proof.** We first use the expression in Equation (1) on the left-hand side:

$$
LHS = \mathbb{E}_{v \sim T} \left[ \sum_{\sigma \in S_t} \mathbb{E}_{k \in \{0,1\}^n} \left[ \left( (Z^k \otimes I_m)^{\otimes \ell} \otimes I_{n+m}^{\otimes t-\ell} \right) |v\rangle \langle \sigma(v)| \left( (Z^k \otimes I_m)^{\otimes \ell} \otimes I_{n+m}^{\otimes t-\ell} \right) \right] \right]. \tag{2}
$$

Then from the previous lemma (Lemma 2.15)

$$(2) = \mathbb{E}_{v \sim T} \left[ \sum_{\sigma_1, \sigma_2 \in S_{t-\ell}} |v\rangle \langle \sigma_1 \circ \sigma_2(v)| \right]
= \mathbb{E}_{v \sim T} \left[ \sum_{\sigma_1 \in S_t} |v_{[1:\ell]}\rangle \langle \sigma_1(v_{[1:\ell]})| \otimes \sum_{\sigma_2 \in S_{t-\ell}} |v_{[\ell+1:t]}\rangle \langle \sigma_2(v_{[\ell+1:t]})| \right]
= \mathbb{E} \left[ \sum_{\sigma_1 \in S_t} |v_1\rangle \langle \sigma_1(v_1)| \otimes \sum_{\sigma_2 \in S_{t-\ell}} |v_2\rangle \langle \sigma_2(v_2)| \right]_{X \subset T, v_1 \sim T, v_2 \sim T \setminus X}
= \mathbb{E}_{X \subset T} \left[ |X\rangle \langle X| \otimes |T \setminus X\rangle \langle T \setminus X| \right].$$

For the first equality, we use Lemma 2.15 and decompose $\sigma = \sigma_1 \circ \sigma_2$ for some $\sigma_1, \sigma_2$ such that $\sigma_1(x) = x$ for all $x \in \{\ell+1, \ell+2, \cdots, t\}$ and $\sigma_2(y) = y$ for all $y \in \{1, 2, \cdots, \ell\}$, which uniquely correspond to elements in $S_t$ and $S_{t-\ell}$. The second equality follows by denoting the first $\ell$ part of $v$ by $v_{[1:\ell]}$ and the last $t-\ell$ part of $v$ by $v_{[\ell+1:t]}$. The third equality holds because sampling $v$ from $T$ is equivalent to sampling $X \subset T$ followed by assigning order to elements in $X$ and in $T \setminus X$.

\[ \square \]

### 3 $\ell$-copy statistical PRS in the CHS model

In this section, we discuss the construction of $\ell$-copy statistical PRS in the CHS model for $\ell = O(\lambda/\log(\lambda)^{1+\epsilon})$ (for any constant $\epsilon > 0$) and length of the common Haar state $n \geq \lambda$. We also show that the construction satisfies multikey security for the same parameters. Further, we complement our result by showing that for $n = \omega(\log(\lambda))$, achieving an $\ell$-copy statistical PRS in the CHS model for $\ell = \Omega(\lambda/\log(\lambda))$ is impossible (similarly for the multikey case), this shows that our construction is optimal (best one can hope for) for $n \geq \lambda$.

**Theorem 3.1.** For all constants $\epsilon > 0$, there exists multi-key $O(\lambda/\log(\lambda)^{1+\epsilon})$-copy statistical stretch PRS in the CHS model.

\footnote{Since $T$ is collision-free, we can interpret it as a set.}
3.1 Construction

In this section, we assume that \( n(\lambda) \geq \lambda \). We define the construction as follows: on input \( k \in \{0,1\}^\lambda \) of the \( n \)-qubit common Haar state \( |\vartheta\rangle \),

\[
G_k(|\vartheta\rangle) := (Z^k \otimes I_{n-\lambda})|\vartheta\rangle.
\]

Note that when \( n(\lambda) > \lambda \), our construction is a stretch PRS.

**Lemma 3.2** (Pseudorandomness). Let \( G \) be as defined above. Let

\[
\rho := \mathbb{E}_{k \leftarrow \{0,1\}^\lambda \mid \vartheta \leftarrow H_n} [G_k(|\vartheta\rangle)^{\otimes \ell} \otimes |\vartheta\rangle^{\otimes \ell}] \quad \text{and} \quad \sigma := \mathbb{E}_{|\varphi\rangle \leftarrow H_n \mid \vartheta \leftarrow H_n} [|\varphi\rangle^{\otimes \ell} \otimes |\vartheta\rangle^{\otimes \ell}] .
\]

Then \( \text{TD}(\rho, \sigma) = O\left(\frac{(\ell+\ell^2)^2}{2^n}\right) \).

**Proof.** We prove this using hybrid arguments:

**Hybrid 1.** Sample \( T \leftarrow [0: \ell+\ell^2]^{2n} \). Sample \( k \leftarrow \{0,1\}^\lambda \). Output \((Z^k \otimes I_{n-\lambda})^{\otimes \ell} \otimes I_n^{\otimes \ell})|T\rangle\).

**Hybrid 2.** Sample \( T \leftarrow [0: \ell+\ell^2]^{2n} \) uniformly conditioned on \( T \in T^{(\ell)}_{\lambda, n-\lambda}(\ell+\ell) \). Sample \( k \leftarrow \{0,1\}^\lambda \). Output \((Z^k \otimes I_{n-\lambda})^{\otimes \ell} \otimes I_n^{\otimes \ell})|T\rangle\).

**Hybrid 3:** Sample \( T \leftarrow [0: \ell+\ell^2]^{2n} \) uniformly conditioned on \( T \in T^{(\ell)}_{\lambda, n-\lambda}(\ell+\ell) \). Sample a uniform \( \ell \)-subset \( T_1 \) from \( T \). Output \(|T_1\rangle \otimes |T \setminus T_1\rangle\).

**Hybrid 4:** Sample \( T \leftarrow [0: \ell+\ell^2]^{2n} \). Sample a uniform \( \ell \)-subset \( T_1 \) from \( T \). Output \(|T_1\rangle \otimes |T \setminus T_1\rangle\).

**Hybrid 5:** Sample a collision-free \( T \) from \([0: \ell+\ell^2]^{2n}\). Sample a uniform \( \ell \)-subset \( T_1 \) from \( T \). Output \(|T_1\rangle \otimes |T \setminus T_1\rangle\).

**Hybrid 6:** Sample a uniform collision-free \( T_1 \) from \([0: \ell]^{2n}\). Sample a uniform collision-free \( T_2 \) from \([0: \ell]^{2n}\) conditioned on \( T_1 \) and \( T_2 \) have no common elements. Output \(|T_1\rangle \otimes |T_2\rangle\).

**Hybrid 7:** Sample a uniform collision-free \( T_1 \) from \([0: \ell]^{2n}\). Sample a uniform collision-free \( T_2 \) from \([0: \ell]^{2n}\). Output \(|T_1\rangle \otimes |T_2\rangle\).

**Hybrid 8:** Sample \( T_1 \leftarrow [0: \ell]^{2n} \). Sample \( T_2 \leftarrow [0: \ell]^{2n} \). Output \(|T_1\rangle \otimes |T_2\rangle\).

By **Lemma 2.14**, the trace distance between Hybrid 1 and Hybrid 2 is \( O((t+\ell)^2 t^2/2^n) \). From **Lemma 2.16**, the output of Hybrid 2 is

\[
\mathbb{E}_{T \leftarrow [0: \ell]^{2n}} \mathbb{E}_{T_1 \subseteq T} \left[ |T_1\rangle \langle T_1| \otimes |T \setminus T_1\rangle \langle T \setminus T_1| \right] .
\]

Hence, Hybrid 2 is equivalent to Hybrid 3. From now on, we will prove the closeness of the remaining hybrids by classical arguments. Again by **Lemma 2.14**, the trace distance between Hybrid 3 and Hybrid 4 is \( O((t+\ell)^2 t^2/2^n) \). The trace distance between Hybrid 4 and Hybrid 5 is \( O((t+\ell)^2/2^n) \) by collision bound. Hybrid 5 and Hybrid 6 are equivalent. The trace distance between Hybrid 6 and Hybrid 7 is \( O(t^2/2^n) \). Finally, the trace distance between Hybrid 7 and Hybrid 8 is \( O((t^2 + \ell^2)/2^n) \) by collision bound. Collecting the probabilities completes the proof.

\[\square\]

\[\text{Since } T \text{ might have collision, } T_1 \text{ is a multiset of size } \ell.\]
Remark 3.3. From Lemma 3.2, we conclude that the construction given above is an \( \ell \)-copy statistical PRS in the CRHS model for \( \ell = O(\lambda / \log(\lambda)^{1+\epsilon}) \) (for any constant \( \epsilon > 0 \)).

By the following lemma, we can also show that the above construction is a multi-key \( \ell \)-copy statistical PRS in the CRHS model for \( \ell = O(\lambda / \log(\lambda)^{1+\epsilon}) \) (for any constant \( \epsilon > 0 \)):

Lemma 3.4 (Multi-key pseudorandomness). Let \( G \) be as defined above. Let

\[
\rho := \bigotimes_{i=1}^{p} \mathbb{E}_{|\varphi_i\rangle \leftarrow H_n} \left[ |\varphi_i\rangle \langle \varphi_i|^{\otimes t} \right] \otimes \mathbb{E}_{|\theta\rangle \leftarrow H_n} \left[ |\theta\rangle \langle \theta|^{\otimes t} \right]
\]

and

\[
\sigma := \mathbb{E}_{|\theta\rangle \leftarrow H_n} \left[ \bigotimes_{i=1}^{p} \mathbb{E}_{k_i \leftarrow \{0,1\}^{\lambda}} \left[ G_{k_i}(|\theta\rangle)^{\otimes t} \right] \otimes |\theta\rangle \langle \theta|^{\otimes t} \right].
\]

Then \( \text{TD}(\rho, \sigma) = O\left( \frac{(p\ell+t)^{2\epsilon}}{2^\lambda} \right) \).

Proof. For \( j = 0, 1, \ldots, p \), we define the following (hybrid) density matrices:

\[
\xi_j := \mathbb{E}_{|\varphi_j\rangle \leftarrow H_n} \left[ |\varphi_j\rangle \langle \varphi_j|^{\otimes t} \right] \otimes \mathbb{E}_{|\theta\rangle \leftarrow H_n} \left[ \bigotimes_{i=j+1}^{p} \mathbb{E}_{k_i \leftarrow \{0,1\}^{\lambda}} \left[ G_{k_i}(|\theta\rangle)^{\otimes t} \right] \otimes |\theta\rangle \langle \theta|^{\otimes t} \right].
\]

We will complete the proof by showing that \( \text{TD}(\xi_j, \xi_{j+1}) = O\left( \frac{(p-j)\ell+t)^{2\epsilon}}{2^\lambda} \right) \) for \( j = 0, 1, \ldots, p-1 \). By the property that \( \text{TD}(A \otimes X, A \otimes Y) = \text{TD}(X, Y) \), the trace distance between \( \xi_j \) and \( \xi_{j+1} \) is identical to that of

\[
\xi'_j := \mathbb{E}_{|\phi_{j+1}\rangle \leftarrow H_n} \left[ |\phi_{j+1}\rangle \langle \phi_{j+1}|^{\otimes t} \right] \otimes \mathbb{E}_{|\phi_{j+1}\rangle \leftarrow H_n} \left[ \bigotimes_{i=j+1}^{p} \mathbb{E}_{k_i \leftarrow \{0,1\}^{\lambda}} \left[ G_{k_i}(|\phi_{j+1}\rangle)^{\otimes t} \right] \otimes |\phi_{j+1}\rangle \langle \phi_{j+1}|^{\otimes t} \right].
\]

and

\[
\xi'_{j+1} := \mathbb{E}_{|\phi_{j+1}\rangle \leftarrow H_n} \left[ |\phi_{j+1}\rangle \langle \phi_{j+1}|^{\otimes t} \right] \otimes \mathbb{E}_{|\phi_{j+1}\rangle \leftarrow H_n} \left[ \bigotimes_{i=j+2}^{p} \mathbb{E}_{k_i \leftarrow \{0,1\}^{\lambda}} \left[ G_{k_i}(|\phi_{j+1}\rangle)^{\otimes t} \right] \otimes |\phi_{j+1}\rangle \langle \phi_{j+1}|^{\otimes t} \right].
\]

By the monotonicity of trace distance (i.e., \( \text{TD}(\mathcal{E}(X), \mathcal{E}(Y)) \leq \text{TD}(X, Y) \) for any quantum channel \( \mathcal{E} \)) and setting \( \mathcal{E} := \bigotimes_{j=0}^{p} \mathbb{E}_{k_j \leftarrow \{0,1\}^{\lambda}} \left[ G_{k_j}(|\cdot\rangle)^{\otimes t} \right] \), \( X \), we have

\[
\text{TD}(\xi'_j, \xi'_{j+1}) \leq \text{TD} \left( \bigotimes_{k_{j+1} \leftarrow \{0,1\}^{\lambda}, |\phi_{j+1}\rangle \leftarrow H_n} \left[ G_{k_{j+1}}(|\phi_{j+1}\rangle)^{\otimes t} \otimes |\phi_{j+1}\rangle \langle \phi_{j+1}|^{\otimes (p-j-1)\ell+t} \right] \right), \]

\[
= O \left( \frac{(p-j)\ell+t)^{2\epsilon}}{2^\lambda} \right),
\]

where the last equality follows from Lemma 3.2. Applying the triangle inequality completes the proof.

As a remark, note that Lemma 3.2 gives a simpler proof of the following theorem in [Col23]:

Lemma 3.5 ([Col23, Lemma 5]). Consider the ensemble of states:

\[
\{ \rho_x \}_{x \in \{0,1\}^n} := \left\{ \mathbb{E}_{|\psi\rangle \leftarrow H_n} \left[ (Z^x \otimes I^{\otimes m})|\psi\rangle \langle \psi|^{\otimes (m+1)} (Z^x \otimes I^{\otimes m}) \right] \right\}_{x \in \{0,1\}^n}.
\]

\footnote{Similar to proving the output of a classical PRG on polynomial i.i.d uniform keys is computationally indistinguishable from polynomial i.i.d uniform strings, we can construct a security reduction to simulate these hybrids. However, since we are in the information-theoretic setting, we instead calculate their trace distances directly.}

\footnote{The channel \( \mathcal{E} \) acts as the identity on unspecified registers.}
Then, there is a constant $C > 0$, such that, for any POVM $\{M_x\}_{x \in \{0,1\}^n}$,

$$x \xleftarrow{\{0,1\}^n} \mathbb{E}_{x \leftarrow \{0,1\}^n} \text{Tr}(M_x \rho_x) = C \cdot \left( \frac{m}{2^m} + \frac{m^2}{2^{3m}} \right).$$

By setting $\ell = 1, t = m, n = \lambda$ in Lemma 3.2 and a hybrid, the success probability is at most $O(m^2/2^n)$ plus the probability of inverting $x$ when the input is $\sigma$, which is at most $1/2^n$ since $\sigma$ is independent of $x$.

In Appendix A, we further give another proof by simplifying the calculation in Lemma 3.5, which may be of independent interest. Moreover, we eliminate the $m^2/2^{3n}$ term.

### 3.2 Impossibility of a special class of PRS in CHS model

In this subsection, if the PRS generation algorithm uses only one copy of the common Haar state, we show that $\ell$-copy statistical PRS and multi-key $\ell$-copy statistical PRS are impossible for $\ell = \Omega(\lambda/\log(\lambda))$ and $n = \omega(\log(\lambda))$.

**Theorem 3.6.** $\ell$-copy statistical PRS is impossible in the CHS model if (a) the generation algorithm uses only one copy of the common Haar state, (b) $\ell = \Omega(\lambda/\log(\lambda))$ and (c) the length of the common Haar state is $\omega(\log(\lambda))$.

**Proof.** We prove this by showing that for $t(\lambda) := \lambda^3$ and $\ell(\lambda) := \lambda/\log(\lambda)$, there exists a (computationally unbounded) adversary $A$ such that

$$\left| \Pr_{k \leftarrow \{0,1\}^k, |\vartheta\rangle \leftarrow \mathcal{H}_n} [A(|\vartheta\rangle \langle \vartheta|^{\otimes t} \otimes G(k, |\vartheta\rangle \langle \vartheta|)] = 1] - \Pr_{|\varphi\rangle \leftarrow \mathcal{H}_n} [A(|\varphi\rangle \langle \varphi|^{\otimes t} = 1] \right|$$

is non-negligible. For short, we use the following notation:

$$\rho_0 := \mathbb{E}_{k \leftarrow \{0,1\}^k, |\vartheta\rangle \leftarrow \mathcal{H}_n} [|\vartheta\rangle \langle \vartheta|^{\otimes t} \otimes G(k, |\vartheta\rangle \langle \vartheta|)]$$

and

$$\rho_1 := \mathbb{E}_{|\varphi\rangle \leftarrow \mathcal{H}_n, |\vartheta\rangle \leftarrow \mathcal{H}_n} [|\vartheta\rangle \langle \vartheta|^{\otimes t} \otimes |\varphi\rangle \langle \varphi|^{\otimes t}].$$

The adversary $A$ is simple: it performs a binary measurement $\{\Pi, I - \Pi\}$ on input $\rho_b$ for $b \in \{0,1\}$, where $\Pi$ is the projection onto the eigenspace of $\rho_0$. The rank of $\rho_0$ and $\rho_1$ satisfies

$$\text{rank}(\rho_0) \leq 2^\lambda \cdot \left( \frac{2^n + \ell + t - 1}{t + \ell} \right) \quad \text{and} \quad \text{rank}(\rho_1) = \left( \frac{2^n + \ell - 1}{\ell} \right) \cdot \left( \frac{2^n + t - 1}{t} \right).$$

Now, by construction, we have

$$\Pr_{k \leftarrow \{0,1\}^k, |\vartheta\rangle \leftarrow \mathcal{H}_n} [A(|\vartheta\rangle \langle \vartheta|^{\otimes t} \otimes G(k, |\vartheta\rangle \langle \vartheta|)] = 1] = \text{Tr}(\Pi \rho_0) = \text{Tr}(\rho_0) = 1.$$

On the other hand, suppose $\Pi = \sum_{i=1}^{\text{rank}(\rho_0)} |u_i\rangle \langle u_i|$, then

$$\Pr_{|\varphi\rangle \leftarrow \mathcal{H}_n, |\vartheta\rangle \leftarrow \mathcal{H}_n} [A(|\varphi\rangle \langle \varphi|^{\otimes t} = 1] = \text{Tr}(\Pi \rho_1) \leq \sum_{i=1}^{\text{rank}(\rho_0)} \frac{1}{(2^n + \ell - 1)} \cdot \sum_{T_1 \in [0:2^n], T_2 \in [0:2^n]} |(T_1 \otimes T_2)|u_i|^2$$
\[
\frac{\text{rank}(\rho_0)}{\text{rank}(\rho_1)} \leq \frac{\text{rank}(\rho_0)}{\text{rank}(\rho_1)} \leq \frac{\text{rank}(\rho_0)}{\text{rank}(\rho_1)}.
\]

A direct calculation yields:

\[
\frac{\text{rank}(\rho_0)}{\text{rank}(\rho_1)} = \frac{2^\lambda \cdot \ell \cdot \prod_{i=0}^{\ell-1} \left(1 + \frac{t}{2^n + i}ight)}{2^\lambda \cdot \ell \cdot \prod_{i=0}^{\ell-1} \left(1 + \frac{t}{2^n + i}\right)} \leq \frac{2^\lambda \cdot \ell \cdot \prod_{i=0}^{\ell-1} \left(1 + \frac{t}{2^n + i}\right)}{2^\lambda \cdot \ell \cdot \prod_{i=0}^{\ell-1} \left(1 + \frac{t}{2^n + i}\right)}.
\]

where the first inequality follows from \((\ell+i)^t \geq (\ell+i)^t\). For \(n = \omega(\log(\lambda))\), \(t = \lambda^3\) and \(\ell = \lambda / \log(\lambda)\), we have

\[
2^\lambda \cdot \left(1 + \frac{t}{2^n}\right) = \left(\frac{\lambda \cdot (1 + \frac{\lambda^3}{\lambda^2 \log(\lambda)})}{1 + \lambda^2 \log(\lambda)}\right)^{\lambda / \log(\lambda)} \leq \left(\frac{\lambda \cdot 2}{\lambda^2 \log(\lambda)}\right)^{\lambda / \log(\lambda)} \leq 2^{-\lambda}
\]

for sufficiently large \(\lambda\). Hence, the distinguishing advantage \((1 - 2^\lambda)\) is non-negligible. This completes the proof.

Note that since \(\ell\)-copy statistical PRS in the CHS model implies multi-key \(\ell\)-copy statistical PRS in the CHS model, we also have the following:

**Theorem 3.7.** Multi-key \(\ell\)-copy statistical PRS is impossible in the CHS model if (a) the generation algorithm uses only one copy of the common Haar state, (b) \(\ell = \Omega(\lambda / \log(\lambda))\) and (c) the length of the common Haar state is \(\omega(\log(\lambda))\).

**Proof.** Since \(\ell\)-copy statistical PRS in the CHS model implies multi-key \(\ell\)-copy statistical PRS in the CHS model, by Theorem 3.6, multi-key \(\ell\)-copy statistical PRS is impossible in CHS model for \(\ell = \Omega(\lambda / \log(\lambda))\).

### 4 Quantum commitments in CHS model

In this section, we construct a commitment scheme that satisfies poly-copy statistical hiding and statistical sum-biding in the CHS model. The scheme is inspired by the quantum commitment scheme proposed in [MY21], adapting it to the CHS model and providing a formal proof of its security. In contrast to the scheme in [MY21], our construction is not in the canonical form [Yan22]. Hence, we need SWAP tests to verify rather than uncomputing, this makes the proof of binding more involved. Our scheme relies on the multi-key pseudorandomness property of the construction giving in Section 3.1 for hiding.

#### 4.1 Construction

We assume that \(n(\lambda) \geq \lambda + 1\) for all \(\lambda \in \mathbb{N}\). Our construction is shown in Figure 1.

#### 4.2 Proof of Correctness, Hiding, and Binding

Clearly, the construction given in Figure 1 has perfect correctness.

**Theorem 4.1.** The construction given in Figure 1 satisfies poly-copy statistical hiding and statistical sum binding.

**Proof of Theorem 4.1.**

**Poly-copy statistical hiding.** It follows immediately from Lemma 3.4 by setting \(\ell = 1\).
Commit phase: The committer $C_\lambda$ on input $b \in \{0,1\}$ does the following:
- Use $p(\lambda) = \lambda$ copies of the common Haar state $|\vartheta\rangle$ to prepare the state $|\Psi_b\rangle_{CR} := \bigotimes_{i=1}^{p}|\psi_b\rangle_{C_i R_i}$, where
  \[
  |\psi_0\rangle_{C_i R_i} := \frac{1}{\sqrt{2^\lambda}} \sum_{k \in \{0,1\}^\lambda} (Z^k \otimes I_{n-\lambda})|\vartheta\rangle_{C_i}|k\rangle_{R_i} \]
  and
  \[
  |\psi_1\rangle_{C_i R_i} := \frac{1}{\sqrt{2^{m_i}}} \sum_{j \in \{0,1\}^m} |j\rangle_{C_i}|j\rangle_{R_i},
  \]
  and $C := (C_1, C_2, \ldots, C_p)$ and $R := (R_1, R_2, \ldots, R_p)$.
- Send the register $C$ to the receiver.

Reveal phase:
- The committer sends $b$ and the register $R$ to the receiver.
- The receiver prepares the state $|\Psi_b\rangle_{C'R'} = \bigotimes_{i=1}^{p}|\psi_b\rangle_{C'_i R'_i}$ by using $p$ copies of the common Haar state $|\vartheta\rangle$, where $C' := (C_1', C_2', \ldots, C_p')$ and $R' := (R_1', R_2', \ldots, R_p')$ are receiver’s registers.
- For $i \in [p]$, the receiver performs the SWAP test between registers $(C_i, R_i)$ and $(C'_i, R'_i)$.
- The receiver outputs $b$ if all SWAP tests accept; otherwise, outputs $\perp$.

Figure 1: Commitment scheme in the CHS model

**Statistical sum binding.** For any (fixed) common Haar state $|\vartheta\rangle$ and $i \in [p]$, it holds that

\[
F(\text{Tr}_{R_i}(|\psi_0\rangle\langle\psi_0|_{C_i R_i}), \text{Tr}_{R_i}(|\psi_1\rangle\langle\psi_1|_{C_i R_i})) = F \left( \frac{1}{2^\lambda} \sum_{k \in \{0,1\}^\lambda} (Z^k \otimes I_{n-\lambda})|\vartheta\rangle\langle\vartheta|_{C_i}(Z^k \otimes I_{n-\lambda}), \frac{I_{C_i}}{2^n} \right)
\]

\[
= 2^{-n} \cdot \text{Tr}(\sqrt{\rho_0})^2 \\
\leq 2^{-n} \cdot \text{rank}(\sqrt{\rho_0}) \cdot \text{Tr}(\rho_0) \\
\leq 2^{-n} \cdot 2^\lambda \cdot 1 = 2^{-(n-\lambda)},
\]

where the second equality is by the definition of fidelity $F(\rho, \sigma) = (\text{Tr}(\sqrt{\rho \sigma} \sqrt{\rho}))^2$; the first inequality follows from $\text{Tr}(\rho^2) \leq \text{rank}(\rho) \cdot \text{Tr}(\rho^2)$ for $\rho \succeq 0$; the second inequality is because $\text{rank}(\sqrt{\rho}) = \text{rank}(\rho)$ for $\rho \succeq 0$ and $\text{rank}(X + Y) \leq \text{rank}(X) + \text{rank}(Y)$.

Let $M^{(b)}_{CR}$ be the POVM operator corresponding to that the receiver outputs $b$ (i.e., all the SWAP tests accept),

\[
M^{(b)}_{CR} := \bigotimes_{i \in [p]} \left( \frac{I_{C_i R_i} + |\psi_b\rangle\langle\psi_b|_{C_i R_i}}{2} \right) = \prod_{S \subseteq [p]} \left[ \bigotimes_{i \in S} |\psi_b\rangle\langle\psi_b|_{C_i R_i} \otimes \bigotimes_{i \notin S} I_{C_i R_i} \right].
\]
For any fixed $S$ is a uniformly random subset of $[p]$. Then the probability that the receiver outputs $b$ is

$$p_b := \text{Tr} \left( M_{CR}(b) \text{Tr}_{E} (U^{(b)}_{RE} |\Phi\rangle \langle \Phi|_{CRE} U^{(b)}_{RE}) \right)$$

$$= \mathbb{E}_{S \subseteq [p]} \left[ \text{Tr} \left( \bigotimes_{i \in S} |\psi_i\rangle \langle \psi_i|_{C,R_i} \otimes \bigotimes_{i \notin S} I_{C,R_i} \otimes \rho_{CR}^{(b)} \right) \right]$$

where $\mathbb{E}$ is the expectation operator, $|\Phi\rangle_{CRE}$ is the malicious committer’s initial state that might depend on $|\theta\rangle$ (we omit the dependence for simplicity), and $U^{(b)}_{RE}$ is the malicious committer’s attacking unitary for $b$; we plug in the definition of $M^{(b)}_{CR}$ and use the short-hand notation $\rho^{(b)}_{CR}$ to obtain the second equality.

For any fixed $S \subseteq [p]$, we have

$$p_{0,S} + p_{1,S}$$

$$= F \left( \bigotimes_{i \in S} |\psi_0\rangle \langle \psi_0|_{C,R_i}, \text{Tr}_{C,R_i; i \notin S} (\rho^{(0)}_{CR}) \right) + F \left( \bigotimes_{i \in S} |\psi_1\rangle \langle \psi_1|_{C,R_i}, \text{Tr}_{C,R_i; i \notin S} (\rho^{(1)}_{CR}) \right)$$

$$\leq F \left( \bigotimes_{i \in S} \text{Tr}_{R_i} (|\psi_0\rangle \langle \psi_0|_{C,R_i}), \text{Tr}_{C,R_i; i \notin S} (\rho^{(0)}_{CR}) \right) + F \left( \bigotimes_{i \in S} \text{Tr}_{R_i} (|\psi_1\rangle \langle \psi_1|_{C,R_i}), \text{Tr}_{C,R_i; i \notin S} (\rho^{(1)}_{CR}) \right)$$

$$\leq 1 + F \left( \bigotimes_{i \in S} \text{Tr}_{R_i} (|\psi_0\rangle \langle \psi_0|_{C,R_i}), \bigotimes_{i \in S} \text{Tr}_{R_i} (|\psi_1\rangle \langle \psi_1|_{C,R_i}) \right)^{1/2}$$

$$= 1 + \bigotimes_{i \in S} F \left( \text{Tr}_{R_i} (|\psi_0\rangle \langle \psi_0|_{C,R_i}), \text{Tr}_{R_i} (|\psi_1\rangle \langle \psi_1|_{C,R_i}) \right)^{1/2} \leq 1 + 2^{-|S|/(2\lambda)},$$

where the first inequality follows from the fact that taking a partial trace won’t decrease the fidelity; the second inequality is because $\text{Tr}_{R} (\rho^{(0)}_{CR}) = \text{Tr}_{R} (\rho^{(1)}_{CR})$ and $F(\rho, \xi) + F(\sigma, \xi) \leq 1 + \sqrt{F(\rho, \xi) F(\sigma, \xi)}$ [NS03]; the last equality follows from the fact that $F(\bigotimes_{i \in S} \rho_i, \bigotimes_{i \in S} \sigma_i) = \prod_{i \in S} F(\rho_i, \sigma_i)$; the last inequality follows from Equation (3).

Finally, we bound the probability $p_0 + p_1$ as follows:

$$p_0 + p_1 = \mathbb{E}_{S \subseteq [p]} [p_{0,S} + p_{1,S}] \leq 1 + \mathbb{E}_{S \subseteq [p]} \left[ 2^{-|S|/(2\lambda)} \right] = 1 + 2^{-p} \sum_{s=0}^{p} \left( \begin{array}{c} p \\ s \end{array} \right) 2^{-s(\lambda - \lambda)}$$

$$= 1 + \left( 1 + 2^{-\lambda} \right)^p = 1 + \text{negl}(\lambda).$$

A Alternative proof of Lemma 3.5

Proof sketch of Lemma 3.5. The first part of the proof is the same as in [Col23]. Here we introduce the required notations and omit the details. Let \( d := 2^n \) and

\[
\sigma := \sum_{x \in \{0,1\}^n} \rho_x = \sum_{x \in \{0,1\}^n} \mathbb{E}_{\mathcal{H}(2^n)} \left[ (Z^x \otimes I^{\otimes m}) |\psi\rangle \langle \psi|^{\otimes m+1} (Z^x \otimes I^{\otimes m}) \right]
\]

\[
= \mathbb{E}_{\mathcal{I}_{d,m+1}} \sum_{x \in \{0,1\}^n} \left[ (Z^x \otimes I^{\otimes m}) |s(\vec{t})\rangle \langle s(\vec{t})| (Z^x \otimes I^{\otimes m}) \right]
\]

\[
= \frac{d}{(m+1)} \cdot \sum_{j \in \{0,1\}^n} \sum_{0 \leq r \leq m} \sum_{\vec{t} \in \mathcal{I}_{j,r}} \frac{r+1}{m+1} |j\rangle \langle j| \otimes |s(\vec{t})\rangle \langle s(\vec{t})|.
\]

So we have

\[
\sigma^{-1/2} = \sqrt{\frac{d}{d+1}} \cdot \sum_{j \in \{0,1\}^n} \sum_{0 \leq r \leq m} \sum_{\vec{t} \in \mathcal{I}_{j,r}} \sqrt{\frac{m+1}{r+1}} |j\rangle \langle j| \otimes |s(\vec{t})\rangle \langle s(\vec{t})|.
\]

Note that \( \sigma^{-1/2} \) is PSD with the largest eigenvalue \( \|\sigma^{-1/2}\| = \left( \frac{d}{m+1} \right) \sqrt{\frac{m+1}{d}} \) (when \( r = 0 \)). In [Col23], the main technicality is to show Equation (28):

\[
\mathbb{E}_{x \leftarrow \{0,1\}^n} \|\rho_x \sigma^{-1/2} \rho_x \sigma^{-1/2}\| \leq C' \cdot \left( \frac{m^7}{d} + \frac{m^7}{d^3} \right),
\]

where \( C' > 0 \) is some constant. Here, we provide an alternative and simpler proof. Since \( \sigma^{-1/2} \) and \( \rho_x \) are both PSD, the matrix \( \sigma^{-1/2} \rho_x \sigma^{-1/2} \) is PSD as well. As \( \rho_x \) is a density matrix, we have

\[
\text{Tr} \left( \rho_x \cdot \sigma^{-1/2} \rho_x \sigma^{-1/2} \right) \leq \left\| \sigma^{-1/2} \rho_x \sigma^{-1/2} \right\|.
\]

Then we use the submultiplicativity of the operator norm to obtain

\[
\|\sigma^{-1/2} \rho_x \sigma^{-1/2}\| \leq \left\| \sigma^{-1/2} \right\| \cdot \left\| Z^x \otimes I^{\otimes m} \right\| \cdot \mathbb{E}_{\mathcal{I}_{d,m+1}} \left[ |s(\vec{t})\rangle \langle s(\vec{t})| \right] \cdot \left\| Z^x \otimes I^{\otimes m} \right\| \cdot \|\sigma^{-1/2}\|
\]

\[
\leq \left\| \sigma^{-1/2} \right\|^2 \cdot \mathbb{E}_{\mathcal{I}_{d,m+1}} \left[ |s(\vec{t})\rangle \langle s(\vec{t})| \right] \quad \text{(unitaries have a unit operator norm)}
\]

\[
= \frac{d+1}{(m+1)} \cdot \frac{d+1}{d} \cdot \frac{1}{(d+m)} = \frac{m+1}{d}.
\]

Hence, it holds that

\[
\mathbb{E}_{x \leftarrow \{0,1\}^n} \text{Tr} \left( \rho_x \sigma^{-1/2} \rho_x \sigma^{-1/2} \right) \leq \frac{m+1}{d}.
\]
